MINING AND SCIENTIFIC PRESS

VOLUME 109

JULY TO DECEMBER
1914

136713
7/9/15

Mining Press
420 MARKET STREET SAN FRANCISCO, CALIFORNIA

INDEX

Page.

A

Abangarez Gold Fields Co., Costa Rica....77, 798
Abbontiakoon Mines, Ltd., West Africa....217, 814, 955
Abbott, James W....Present conditions at Ploche, Nevada ... 483
Abe Lincoln mine, Cripple Creek, Colorado....75, 502, 618, 658
Abosso, West Africa....814, 955
Abrasive materials, United States consumption.... 120
Acacia mine, Cripple Creek, Colorado....423, 502
Accident Commission, California Industrial. See California.
Accident fatalities, U. S. coal mines.... 918
Prevention v. compensation....Frank H. Trego.... 691
Rate, metal mines, U. S.... 586
Accidents, Alaska 820
California Commission report 114
Western Australia, hoisting 878
Accounts, Simple mine 60
Acme, Porcupine, Ontario 573
Adsorption, Phenomena of 451
Advertisements and situations ....Editorial.... 787
Africa, German Southwest, export 239
Agriculture, Department of and Agricultural Society meetings 191
Ditto ....Editorial.... 168
Ahmeek Copper Mining Co., Kearsarge, Michigan ...232, 872
Air compressor, Motor-driven portable 666
Compressor, rotary 624
Compressor, Variable volume 121
Depletion in mines 729
In mines, and gasoline locomotives 608
Ajax Gold Mining Co., Victor, Colorado 618
Ajo ores, Leaching experiments on- I, II, III .... Stuart Croasdale....209, 252, 291
Akoko mine, West Africa 811, 955
Alabama, coal production 631
Coke production 80, 634
Iron, pig, production 634
Metal production 38
Aladdin Mining Co. and Chambers-Ferland Mining Co., Ontario 152
Alaska, accidents 820
Barite deposits near Wrangell ..Ernest F. Burchard.... 371
Bethel district 460
Brond Pass district reported discovery and Stephen Birch 497
Ditto ....Editorial.... 469
Castle islands barite occurrence 348
Chicago Bench suit 422
Chisana district 156, 227, 229, 348, 500, 501, 617
Chisana district map 28
Chisana gold yield 698
Circle district mining 887
Coal-bearing area 308
Coalfields map 342
Coal lands leasing .... Editorial.... 277
Coal lands leasing bill in Senate 498, 571
Cordova district 225
Cordova district, map 199
Coal lands leasing bill 615
Dogmobiles ....Editorial.... 239
Dredging 720
Eagle district mining 888
Fairbanks district gold production 422
Fairbanks district, placer mining ....E. E. Hurja.... 965
Fairbanks district production 966
Glaciers 67
Gold production 590
Government railways 156
Hydraulicking 886
Iditarod district gold production 656
Iditarod-Ruby district 656
Innoko district gold production 656
Iskoot River district 69
Juneau district history and outlook 152
Ketchikan district 734
Ketchikan district and war 617
Ketchikan district, Mining revival in the..E.E.Hurja.... 10
Klondike district dredging 451
Koyukuk mining district ....E. E. Hurja.... 416
Kuskokwim River district 656
Map of 422
Mineral production 820
'Mineral Resources of Alaska' 776
Mining in the Far North....Emil Edward Hurja.... 10, 69, 103, 152, 225, 261, 568, 769, 848, 887, 965
Nelchina district 657
Nizina district 226, 500
Nome beaches 910
Nome business 1006
Placer act decision ....Editorial.... 1
Petroleum production 935
Railroad 348
Railways surveys report 734
Ruby District gold production 656
Ruby-Innoko-Iditarod gold districts 534
Seventymile District mining 888
Seward and the Kenai peninsula ....E. E. Hurja.... 341
Seward Peninsula and its mining problems.... F. Lynwood Garrison.... 907

Page.

Alaska, Seward Peninsula gold production 734
Sinrock iron deposit 1006
Tanana River district 965
Tin deposits ....Editorial.... 791
Tolovana district gold discovery 855
U. S. Geol. Survey work 973
Valdez and Prince William Sound .... Emil Edward Hurja.... 261
Willow Creek district, Cyaniding tailing.... J. T. Terry, Jr.... 989
Woodchopper Creek district 888, 892
Wrangell mining district 69
Yukon river drainage area 422
Alaska Consolidated Copper Co.... 226
Alaska Crow Creek Mining Co.... 343
Alaska Ebner Gold Mines Co.... 152
And Consolidated California-Nevada Co.... 927
Alaska Gastineau Mining Co. 152, 973
Developments of the ....E. E. Hurja.... 103
Perseverance mine concrete head-frame .... C. T. Jackson.... 99
Alaska Gold Mines Co....309, 572, 973
Company report.... 657
Developments of the ....E. E. Hurja.... 103
Sheep Creek tunnel 694
Alaska Juneau Gold Mining Co.... 152
Alaska Mexican Gold Mining Co..153, 193, 348, 422, 534, 698, 855
Alaska Oil & Refining Co.... 227
Alaska Syndicate, Bonanza mine 499
Jumbo mine 499
Alaska Treadwell Gold Mining Co. ..152, 193, 348, 422, 501, 534, 698, 855, 973
Accident 820
Cyanide plant, Concentrate treatment costs.... W. P. Lass.... 960
Alaska United Copper Exploration Co...193, 226, 348, 422, 499, 534, 698, 892
Alaska Venture Syndicate, Ltd.... 11, 617
Alboline and petroleum production 693
Alexo nickel mine, Ontario 504, 977
Algoma Steel Corporation 421
Alice Gold & Silver Mining Co. v. Anaconda Copper Mining Co. 27
Alkalinity estimations 188
Allen, A. W. ....Milling in cyanide.... 377
Ditto....Northwestern Australia and its mineral resources 321
Ditto....Solution control in cyanidation.... 527
Ditto....Titration results in cyanidation.... 247
Alliance Mining Co., Republic, Washington, and Anaconda Gold Mining & Reduction Co. 896
Allis-Chalmers Mfg. Co., Little Wonder battery stem guides 584
Allouez Mining Co., Allouez, Michigan 232, 874
Alloy, antimony in 846
Gold and silver 188
Silver-copper 188
U. S. production 102
Van Gundy 22
Alps Mining Co., Ploche, Nevada 485
Alsace-Lorraine, Germany, mining.... 451
Alta Consolidated Mining Co., Alta, Utah 537
Alta Tunnel & Transportation Co.... 895
Aluminum, alloy for silver 415
Prices 199, 388, 541, 704, 781
Relative natural and commercial scarcity of the metals Edwin C. Eckel.... 182
U. S. production 861
Amalgamated Copper Co., Montana 652
Amalgamated Ploche Mines & Smelters Corporation, Ploche, Nevada 462, 483
Amalgamated Zinc (De Bavay's), Ltd., Broken Hill, New South Wales, company report 724, 1013
Amalgamation, Rhodesia 188
Silver ores 300
South Dakota mills 924
Amber 924
Germany, East Prussia production 924
America, Production of radium .... Charles H. Viol.... 443
American dredges for foreign countries ....Editorial.... 432
American Association of State Geologists ...Editorial.... 319
American Brass Co.... 420
American Committee, The ....Editorial.... 669
American Cyanamid Co.... 854
American Exploration Co., Park City, Utah....233, 312, 1010
American Flag mines, Utah 233, 312, 1010
American Girl mine, Arizona 892
American Gold-Copper Mining Co., New Mexico.... 819
American Institute of Chemical Engineers, Philadelphia and ....George Otis Smith.... 906
American Institute of Mining Engineers and Congress ....Editorial.... 169
Pittsburgh meeting, Bureau of mines experimental mine 877
Pittsburgh meeting ....Editorial.... 509
Ditto ....Editorial correspondence.... 588
Salt Lake City meeting 301
Ditto ....Editorial....125, 239
San Francisco section .... Editorial.... 586
American Locomotive Co. notes taken up ....Editorial.... 125
American Meerschaum & Pipe Corporation, New Mexico .. 819

Page.

American Mining Co., California 423
American Mining Congress, Phoenix meeting.....574, 869
Ditto .....Editorial....585, 788, 903
President Wilson's letter 906
American Museum of Safety, Safety and Sanitation Conference, New York 1005
American Nettie mine, Colorado 822
American Petroleum Society .....Editorial.... 86
American Rutile Co., Roseland, Virginia.....Editorial.... 983
American Smelting & Refining Co. 272, 536
Ditto .....Editorial.... 585
And Riverside Dairy & Stock Farm 537
Chihuahua plant 77, 774
Chihuahua smelter .....Editorial.... 125
Company report 497, 581
Copper prices 662
Lead production 889
Mexican plants 419, 458
v. Federal Mining & Smelting Co., ..Sidney Norman.... 339
American Turquoise Co., New Mexico 819
American Zinc, Lead & Smelting Co., ... 68
Hillshoro, Illinois plant .....E. H. Leslie.... 280
Amur, Gold mining on the.....W. H. Shockley.... 249
Anaconda Copper Mining Co., Butte, Montana..30, 110, 121, 208, 424, 461, 503, 580, 781, 852, 931, 934, 975, 978
Ditto .....Editorial.... 203
And Butte & Duluth 1005
And International Smelting & Refining Co. 816
Barbed wire defense .....Editorial.... 829
Flotation. .....Editorial.... 829
Labor conditions .....Editorial.... 318
Labor union trouble .....Editorial.... 360
Mountain View mine fire 351, 384
Slime concentrator 238
v. Alice Gold & Silver Mining Co. 27
Anaconda Gold Mining Co., Roubaix, South Dakota..... 1005
Anchor Tin Mining Co., Tasmania 65
Andrada Mines, Ltd., Portuguese East Africa, Handling boulders .....L. C. de la Marliere.... 762
Anglo-Westphalian Kent Coalfield, Ltd. 925
Antelope Springs Mining Co., Nevada 975
Anthracite culm 768
Antimony .....Editorial.... 745
Alloys 846
And war 369, 732
Canada, New Brunswick 970
Marketed by brand .....Editorial.... 743
New Zealand production 919
Prices 35, 199, 388, 541, 704, 899
Sulphide ores, process for treating 149
U. S. occurrence 369
U. S. production 861
Uses 847
Antelope Gold Mine, Ltd., Rhodesia 959
Antelope Spring Mining Co., Humboldt, Nevada 576
Anyox mine, Granby Consolidated 615
Apex mines v. Gauf, Rand 73
Application of flotation to gold ores.....John Bevan.... 413
Of jigs to gold dredging .....James W. Neill.... 839
Ditto .....Editorial.... 903
Argall, Phillip ....Siderite and sulphides in Leadville ore deposits—I, II 50, 128
Ditto....Siderite and sulphides in Leadville ore deposits —a correction 148
Argentina, imports and exports 792
Mineral exports 918
Mineral resources 794
Mining in 17
Rosario district, wolfram exports 648
Trade extension to .....Editorial.... 829
Argo Mining, Drainage, Transportation & Tunnel Co., Idaho Springs, Colorado, mill practice 833
Argonaut Mining Co., Jackson, California 157
v. Kennedy Extension Gold Mining Co., decision 28, 61
Arizonia, Ajo copper mining district 383
Ajo diamond-drilling tests 415
Camp revivals 191
Cedar district 574
Cinnabar discovery 156
Employment of foreigners 816
Gila county division proposed 618
Grand Gulch mining district 74
Juniper Flats gold discovery 193
Map 617
Mineral production 74
Mohave county mining districts 855
Phoenix, American Mining Congress 574, 868, 906
Ditto .....Editorial....585, 788, 903
Phoenix, first-aid contest 855
Arizona Commercial Co., Globe, Arizona 114, 229
Arizona Copper Co., Ltd., Morenci, Arizona.....121, 313. 348, 422, 530, 657, 855, 1006
Smelter costs 223
Tax suit 734
Arizona Copper-Gold Mining Co., Arizona 1006
Arkansas, coal production 80
Mineral production 664
Arps and Krisher, Colorado 822
Arsenic in ores, Estimating.....Basil G. Dunstan.... 412
Sulphide ores, process for treating 149
White, U. S. production and consumption.....562, 664, 648
Artificial respiration 765
As war looks in London.....T. A. Rickard.... 320, 362, 394, 434, 472, 547, 868
Ashestos, California production 929
Ashanti mine, West Africa 217, 814, 955
Rainfall 496
Ashio Copper Co., Japan, dust chambers at smelter 13
Asphalt, Alsace-Lorraine production 451
U. S. production and consumption 664
Assay outfit, Portable.....Theo. A. Clack.... 491
Platinum .....Frederick P. Dewey.... 20
Assaying and sampling Cobalt ores 605
Assessment suspension hill, mining..... 652
Work exemption of mines 533

Page.

Assets Realization 68
Assets Realizing Mines Corporation, Los Angeles..... 230
Associated Gold Mines of Western Australia, Ltd., Kalgoorlie, Western Australia, and North Thompson mine, Ontario 819
Company report 315
Associated Northern Blocks, Western Australia, Ltd., Victorious mine, Ora Banda 697
Atlanta Mines Co., Goldfield, Nevada 76
Atlas Mining & Milling Co., Sneffles, Colorado 822, 931
Atolia Mining Co., California 821
Atomic weights for 1915 375
Attempts at domestic tin production .....Editorial.... 790
Augers, pneumatic 378
Aurelia Crown mine, Washington 895
Aurora Consolidated Mines Co., Aurora, Nevada 158, 576
And Goldfield Consolidated Mining Co..... 30
New mill 57, 462
Austin, Arthur, death of 78
Austin, L. S. .....Smelting costs and prices for silver-lead ores 170
Australasia, explosives imports 886
Federated Engine-Drivers' and Firemen's Association.. 876
War effects in .....Editorial.... 471

DECISION of the suit of the Kennedy Extension Mining Company against the Argonaut Mining Company has been rendered and is favorable to the Argonaut. The points at issue were briefly discussed in our issue of January 17, and a full summary of this important case will follow.

GENERAL FELIPE ANGELES and Lic. Luis Cabrera are prominent among those named at the Niagara Falls conference as possible successors of Huerta. As both are Constitutionalists, it is hardly likely that Huerta will accept them and as Carranza has ambitions of becoming president, neither can count upon his support.

CALIFORNIA mine operators will welcome the announcement that the Mine Owners Casualty Indemnity Exchange has been organized in order to reduce the cost of workmen's compensation insurance through coöperation of the mine operators. This is a matter in which we take much interest and that we propose to discuss fully next week. In the meantime inquirers can get full information at the offices of the new company in the First National Bank building, San Francisco.

ALASKANS were especially interested in the decision of the case of Likaits *v.* Johnson construing the Alaska placer act and reported in our issue of June 6. The case arose over use of a power of attorney to locate placer ground. Another case was that of Sutherland *v.* Purdy, reported in May. Briefly, the new law requires that power of attorney, to be effective in placer location, must be recorded within the judicial district in which it is used and limits its use to two locations in any one month. In the one case the recording was not done until after the location was made, though before the second locator filed on the claim, a fact perhaps not made sufficiently clear in our abstract. The court held that the order of the acts was immaterial in view of the good faith shown and the climatic and geographical conditions faced. In the second case the record was improperly made but has held to be good none the less. The judge held that, having in view the actual conditions in the field, when a locator deposits his documents in the proper recording office and pays the recording fee, later receiving the documents back bearing the endorsement of record, he is not liable for any errors or neglect of the recorder. These are sensible business-like decisions in line with the general rule that the mining law is to be interpreted in accordance with the conditions as they are rather than as they might be.

THE NATOMAS fiasco points again to the moral we have often preached; namely, the sound economic basis of the work of independent engineers. The men of the regular staff of the Natomas are highly qualified, but human nature is not to be denied, and as vendors we all see most keenly the strong points of what we have to sell. We have previously referred to mistakes made by the consulting engineer who in this case acted for the London bondholders. He has replied in the *Press* and also in a special report to the stockholders by urging that he merely accepted figures given him by the men on the ground. The very fact that his having done so has involved him in the necessity of making elaborate explanations and excuses, is the best of arguments against an engineer in any such situation accepting critical data at second hand.

CREATION of a petroleum division in the U. S. Bureau of Mines and appointment of Mr. W. A. Williams to be its chief, is in some ways the most important move made by the United States government in its relation to petroleum production in many months. The new division is to have charge of all technologic work connected with oil on the public and Indian lands. As owner of large areas in the midst of productive fields, and of even larger tracts of potential oil land, the Government has a direct interest in securing the most economical development and the maximum yield. Waste of gas and flooding of oil sands is as serious when on public as on private land. In Oklahoma, too, the Secretary of Interior, as guardian for the Indians, has heavy responsibilities in connection with actual production of gas and oil, and if oil is to be produced from public lands by lease or otherwise for the navy, to say nothing of proposals that the Government should build pipelines, there is every reason why the Department should

have on its staff men who really know the oil business. Petroleum producers have complained, not without justification, that in the past, government action has been too often uninformed, or based upon half knowledge. Mr. Williams is a thoroughly competent oil man, a graduate of Stanford University and experienced through service with the Associate and General Petroleum companies. He has the confidence of California operators and may be expected to win that of Eastern petroleum producers as they come to know him. It is understood that $60,000 is available for beginning his work and an amendment to the sundry civil bill has been introduced increasing this sum to $200,000.

REFINANCING NATOMAS

Plans for relieving Natomas Consolidated of California from financial difficulties have been worked out in London and were announced in San Francisco, June 18. In the interest of the new plan, an appeal is being made to bondholders by a committee consisting of Messrs. Frank B. Anderson, Herbert Fleishacker, Percy T. Morgan, George E. Webber, and Curtis H. Lindley; certainly a list of weighty names. Among those active in formulating the plan in London were Mr. Herbert C. Hoover and others of equal standing. Nonetheless opposition has appeared, being voiced by McCutchen, Olney, and Willard, and a formidable revolt on the part of bondholders is not improbable. When a company having a liberal number of conflicting securities gets into financial difficulties, it is hardly to be expected that any plan for reorganization will be accepted without protest. The very condition that makes reorganization necessary, implying as it does some failure or miscarriage of plans, requires that there shall be some sacrifice in order to offset it. With security-holders having unequal interests, it is natural that each should try to save for himself what he can, and equally inevitable that the other parties in interest, if informed and vigilant, should protest. There is abundant room for difference of opinion, and it is possible to discuss these differences, we hope, without imputing to anyone more than the normal desire to save what he may for himself.

It is proposed to organize a new company and to issue $3,000,000 in five-year notes; $16,500,000 in 20-year, 6 per cent, first mortgage bonds, using $4,500,000 of these to secure the five-year notes; $7,250,000 in non-cumulative stock; and $9,250,000 in common stock. The right is reserved to pay the first five years interest on the bonds in bonds of the same series, and $2,500,000 of the issue is held for that purpose. A new English company capitalized at £600,000 is to be formed to hold the common stock. The securities are to be distributed as follows: The Natomas Syndicate will buy the $3,000,000 issue of notes for $2,700,000, and the common stock. Each holder of $1000 of the first mortgage bonds of the present Natomas company will receive $600 in the new bonds and $400 in preferred stock. Each holder of $1000 of second mortgage bonds will receive $500 in preferred stock and £5 in the stock of the English company. Each holder of $100 of stock in Natomas Consolidated will receive £1 in stock of the English company. The floating debt creditors will surrender their securities and take 90-day notes or the new five-year notes at 90 cents. Since the floating debt amounts to $1,088,000 and the debt to the Natomas Syndicate is $1,213,000, it is evident that but little additional cash will become available under this arrangement. The plan proposed is peculiar in that floating debt creditors and holders of junior securities, in return for the advancement of a relatively small amount of additional capital, are to be given preference over first-mortgage bond holders. The latter are asked to consent to receive further bonds in lieu of interest for the next five years. This payment of interest on bonds by issuing more bonds is strongly reminiscent of the nursery rhyme:

> Big bugs have little bugs to bite 'em;
> Little bugs have littler bugs,
> And so on *ad infinitum.*

If, indeed, a plan has been found by which interest on debts can be met by merely creating more debts, a delightful field for financing is opened. Seriously, however, this but postpones the day of reckoning and adds to the interest charge. In the meanwhile, the handling of the property will be in the control of those who have a minor interest, and in five years the best part of the most nearly liquid asset, the gold reserves, will be gone. Whether the market for land will have improved enough to offset this is a question.

The serious matter, the one of general interest, is the light regard paid to the first mortgage bonds. Natomas bonds have been endorsed as suitable for investment of trust funds by bankers standing high in the business world. Now they are swept aside to give piled-up security to those who advance money on short-time notes. Incidentally, it develops that by reason of the issue of reclamation bonds, the first mortgage bonds are in fact now junior securities. No wonder that it was found difficult to make this clear to British bondholders. It is far from lucid to many nearer the home of the Company.

The men and the banks that advanced money this spring to save Natomas from a receivership have a strong claim for preference in the reorganization. By certain of the directors at least, personal securities were advanced to save the Company credit. No adjustment can be satisfactory that does not take into account such claims. But the bondholders also have equities, and back of that is the public interest. There can be no question but that public confidence in Western securities will be seriously injured if Natomas bonds are set aside in this fashion. A bond should stand for something. If as a matter of fact it has come to represent nothing definite, it will be hard hereafter to sell bonds, as it is now hard to sell stocks, and industry will suffer.

It is difficult to determine the real present value of

the various Natomas securities. The concern is an unusual enterprise. In part it is founded on gold-dredging and in part it is a land reclamation scheme. However, speaking in a large way, it is not the land dredged for gold that is being reclaimed by drainage and irrigation. The scheme is much more ingenious than that. Briefly, 9501 acres of gold-dredging land, valued December 31, 1913, at $14,433,532, and estimated by the Company engineers to contain $10,250,634 net, forms the basis of a profitable industry which, with subordinate sums from sale of crushed rock and subsidiary enterprises, has been paying interest on bonds issued to obtain funds for reclaiming valley lands immediately north of Sacramento. In the end it has been planned that the reclaimed lands should be sold at such prices as to afford a profit on the whole enterprise.

The plan has many excellent features. Gold-dredging is a profitable but short-lived enterprise. A gold-dredging field may be quickly equipped and brought into production, and, while the dredging ground lasts, the income will be sufficient to carry a large bond issue, such as is necessary to finance a reclamation project through the long lean years while the land is being brought under cultivation and sold. It has the inherent difficulty that it combines two dissimilar enterprises, both of which are speculative. A speculative enterprise, to assure success, requires special knowledge and close attention, and it is a rare thing for a manager, or even a group of managers, to handle dissimilar businesses equally well. As noted by *The Mining Magazine*, there is even a movement now toward having boards of consulting engineers instead of one for companies engaged exclusively in mining and closely related industries, and it is a well known fact that mining companies only in the rarest instances make money from such agricultural lands as they chance to own. On the other hand, farmers as mine managers have become a byword. To combine gold-dredging and farming is simply to invite disaster.

And disaster came. We have repeatedly directed attention to the fact that estimates made by the Natomas management and the Company's consulting engineer have proved sadly out. The gold-dredging ground owned by the Company has long been known to be valuable, but much of it is cemented and hard to dig. Building a dredge to handle it necessarily involved an experimental element. It is true, probably, that the final outcome is even yet not wholly certain, since the dredges, large and strong as they are, are subjected to unusually heavy strains, and it is too soon to say what their life will be and what is a proper amortization charge. They are magnificent dredges and are performing well, but operating costs for short periods are often deceptive. Delay in equipping the ground with a full fleet is the obvious cause of the disaster that has overtaken the Company; the gold has come from the ground too slowly and in too small amounts, while all the time interest charges were mounting and engineering expenses in connection with the land reclamation were to be met. Re-designing and re-building the dredges was inevitable, although the main lines have not been changed; this, together with a most unusual sequence of fire loss and wrecks, has been responsible for the delay. The fact that it was not anticipated, throws a shadow over the judgment of the engineers concerned and causes bondholders to question everything. This attitude is reinforced by such circumstances as that Mr. E. J. de Sabla, in speaking before the bond and stock holders in London in 1911, estimated the profit for 1913 at $2,000,000; in fact the total was $1,151,887. The net yield from gold-dredging for last year was estimated at $1,350,000, and proved to be $992,366. It is a brave tale of optimistic venture, but a sorry one of estimates and performance.

It is even more difficult to form an estimate of the value of the lands being reclaimed. In round numbers there are 28,000 acres of irrigated lands and 60,000 of reclamation lands. Mr. de Sabla said, in the address quoted, that the land had cost about $25 per acre. This, however, makes but a small fraction of the amount realized from sale of bonds alone, about $8,500,000, and there are still heavy payments on land to be met. That reclamation of land is itself profitable as well as good for the state in which the land lies, has been abundantly proved; provided always that the land be well chosen, the engineering and the estimates sound, and the market reasonably certain and near in point of time. The best lands go begging at times and in places, and interest on money spent in throwing up embankments and putting in drains and irrigating ditches may well eat up the profit on the work if the sale of the land be slow.

Another factor that is not always sufficiently considered is that mere reclamation of land is not all. The expense of preparing it for crops, the building of houses, barns, and fences is considerable, and must all be figured into the cost. It must either be done by the vendor or its cost deducted from the price that would otherwise be paid by purchaser. It is not possible to sell land, in any large way, except upon terms that permit the purchaser to earn good interest on his investment, and it is not always possible to sell even good land promptly. A recent investigation showed that in California the mere cost of selling lands absorbs 40 per cent of the price realized, and the notable failure of California to attract settlers rapidly can undoubtedly be laid to the absurd overvaluation of the lands on the market. An individual may make satisfactory returns from a few acres devoted to some special crop, but a state as large as France with only two-fifths of its population on the farms, must be content to attract settlers on an "alfalfa basis." Improved lands of equal value can be bought in Europe today for less than is being asked in California, while in Canada, Australia, and other new countries settlers are offered the choice of excellent lands at prices still lower. These are facts that must be taken into account when it is proposed to reclaim and market any such area as 80,000 acres. We

would not pose as an expert on agricultural lands. We understand that some Natomas land is of high value; some doubtless is not worth the money spent reclaiming it. Such inequalities are inevitable when great areas are included in a single project. How much is good and how much bad, we do not know, nor are we aware of any certain information available to the public or the bondholders answering this question. According to the Natomas report of December 31, last, a few acres have been leased for a cash rental of $10 per acre, though the larger amount leased is at $2.64 per acre. If all the irrigated and reclamation land be leased at $10 per acre cash rental, the return would still be less than enough to pay 6 per cent interest on the valuation placed on the reclamation lands alone. This would leave it necessary for the gold-dredging properties, valued by the directors at $14,000,000, but now estimated to contain about $10,000,000 net, of which the present value is perhaps half that amount, to care for amortization.

It is difficult to see how the bonds are ever to be paid in full except by the fortuitous influx of an unheard of number of land buyers willing to pay top prices and do it quickly. This may be too pessimistic a view. If so, it is because adequate engineering studies either have not been made or their results are not available to bondholders. Indeed, what is most wanted is more light upon the whole matter. The reorganization committee may indeed be proposing the only possible plan, but the Company is paying dear for a relatively small amount of money, and it is probable that if the whole property were examined and full information given, competition would be invoked and better terms could be made. At any rate, bondholders are now very much in the dark and are asked to act upon information that is entirely inadequate. They should look before they leap.

GOLD EXPORTS

The movement of over $60,000,000 in gold bars and coin from the United States to European countries in the past six months has given rise to general interest and discussion. So far as this country is concerned, this unusual movement does not seem fraught with any profound or sinister significance. The gold reserves of the world are a fluid medium, flowing from the points where the pressure is higher to where it is less, and the movement in one direction at a given time may be speedily followed by a reverse flow a short time later. We buy large quantities of merchandise from foreign countries; we sell even larger quantities to them in return. Large sums must be annually paid to European investors for interest on their holdings in this country, and if the investors wish to leave the money here for investment in new securities, or if they wish to 'take out in trade' our indebtedness to them, international dealings will be marked by large exports of goods from the United States and small exports of specie. On the other hand, if European investors reduce their purchases from us and show a desire to receive their interest return in specie for employment at home, merchandise exports will fall off and specie exports will increase. Such a situation exists at the present time. The uncertain effect of the basic legislation affecting industry now under consideration at Washington, the possibility of a crisis this autumn when the movement of crops of record size makes its annual strain on the financial situation here, and the unfortunate experiences which European holders of American railroad securities have gone through in the past few years, all tend to discourage investment of European money in the United States at this time, while imports of European merchandise have been stimulated by the recent decrease in the import tariffs.

There are other factors in Europe which enter into the situation as well. The specie holdings of the banks in Russia have been increased by $92,500,000 in the past year, standing at $902,113,000 on May 21. The holdings in Germany have been increased to almost an equal amount and now stand at a sum approximately one-half that of the banks in Russia. The adjustment of the Balkan trouble resulted in the practical removal of Turkey from Europe, but at no marked advantage to Russia; a country which urgently needs to gain an outlet to the Mediterranean sea, through the absorption of the territory which stands in her path, or otherwise. Russia has recently made a tremendous increase in the peace footing of her army, and there are those who see in these events the imminent possibility of war between Russia and Germany, the latter country being a strong factor in the political readjustment recently concluded in the Balkan peninsula. This view is certainly not without the bounds of possibility, though we profess no such familiarity with the inner workings of the chancelleries of Europe as would permit us to express a well informed opinion. Austria has also made large increases in her specie holdings, possibly also in preparation for war, as Austria would inevitably be drawn into such a conflict. In France a national loan of $350,000,000 has been authorized to provide, among other things, for military expansion, and the French banks have been building up their gold reserve in preparation. All in all, Europe does not seem at the present moment a desirable feeding ground for the dove of peace. In the face of these conditions, the reserves of the Bank of England have shrunk some $6,000,000 in the past year, although the receipts of bar gold and coin in England for the year ended in April amounted to $300,000,000. The view generally expressed in New York financial circles is that the present movement of gold to Europe practically came to an end with the shipments of specie which arrived in Europe in time for the interest payments due on July 1. Those who think the business situation in America one of extreme difficulty have at least the consolation that the clouds on our financial horizon are not so threatening as those on the other side of the Atlantic.

Methods of Testing Placer Gravels

By W. J. RADFORD

In the bonanza days of placer mining, when only such gravel tracts as were of 'picture book' value were worked, with a no greater monetary outlay than was necessary to build a few sections of sluice box and purchase tools, a very rough pan sampling sufficed to determine whether the gold was present in paying quantities. These days, however, have passed and the present day placer miner is forced to consider the lower grade gravels. To operate low-grade deposits at a profit requires the erection or purchase of plants costing many thousands of dollars. With large sums involved and the lowness of grade to be considered, the examining engineer of today has a much greater responsibility thrust upon him. To meet these new conditions more scientific and accurate systems for testing have been evolved, which are the outcome of years of experiment and experience. Where, in the early days, assays were stated in dollars, they are now estimated in cents per cubic yard, and a few cents difference, one way or the other, may mean the success or failure of an enterprise involving the investment of large sums.

On many occasions I have been asked such questions as the following: 'Of what degree of accuracy are gravel tests?' 'How closely will the estimated gravel value, as determined by examination, check with actual value, as found by operation?' To answer questions of this nature without an intimate knowledge of the tract to be tested is to a certain extent impossible. In such case, one can but refer to the results of operating concerns, each operation having its own peculiar conditions.

Estimated and Actual Value

Before proceeding with a discussion of this subject, it would probably be advisable to explain the sense in which the terms 'estimated value' and 'actual value' are used. By 'estimated value', is here meant the value per cubic yard of the gravel as determined by a series of tests. From this is deducted a certain varying percentage for loss in operation, the result being the estimated value of the gravel in dollars and cents. 'Actual value' is the value per cubic yard as computed from the gross bullion return and the yardage treated.

Theoretically, 'estimated value' and 'actual value' should be the same, but in practice there is found to be a varying percentage of difference. This variation is dependent upon many factors, one or more of which may be the determining cause of the variation in any given case, such as local topography, character of metal content, character of gravel, presence of water, and methods of testing. Yet, even with these changing conditions, a certain uniform ratio should be maintained by adapting the method of testing to local conditions, that is, the method of testing one tract of gravel would not necessarily apply to another. It is here that the personal equation enters into the question: the experience of the examining engineer, together with his faculty for judging conditions, goes a long way toward reducing the difference between 'estimated' and 'actual' value. I shall briefly review the several methods generally used in testing placer deposits, and attempt to show what degree of reliability may reasonably be expected from each, as inferred from experience in placer mining examinations in both North and South America.

Preliminary Pan Testing

This method is used primarily for determining the gold content of a gravel deposit to learn if it will justify further and more careful testing.

The only tools necessary are a standard gold pan, a pick, a shovel, and a two-foot rule or steel tape line. The fundamental requirement, however, is one that the engineer himself must possess, namely, the knowledge requisite to estimate accurately by observation the number of pans of gravel that will equal a cubic yard in place. The number of pans, filled evenly with the top, which will constitute a cubic yard in place varies from 20 to 160, depending upon the degree of coarseness or fineness of the material. About 150 or 160 pans of sand are required to make a cubic yard, while for a very coarse gravel, not more than 20 or 30 are required. An average gravel runs about 60 or 70 pans to the cubic yard. It is upon this point that the secret of obtaining accurate results largely depends, and this knowledge comes only from field experience and experiment. The bank in question may be dealt with as a whole and a figure representing the number of pans to the cubic yard determined, or if there is a very decided variation in the character of the material, as is sometimes the case, it may be treated by strata, in which event each stratum will have its own factor to be applied when that particular stratum is tested.

The method of procedure is as follows: Clean off a face on the bank, say two feet in width and extending from bedrock to top, removing the gravel to at least 6 or 8 inches in depth. This is a precaution that should always be observed if accurate results are desired. In case of leaching or surface concentration, this method insures more correct results, and if there should have been an attempt to salt the gravel, it tends to prevent fraud. For this work, in some cases, it will be convenient to have a ladder, or it may even be necessary to use a rope, allowing one's self to be raised or lowered from above. If the test is to be rough, the samples may be taken in a succession of steps at easily accessible points. Should this method be used, care must be taken not to skip sections of the bank or to overlap, a feature

which it is especially necessary to guard against. Gold, owing to the manner of its deposition, has a very marked tendency to lie in longitudinal streaks, more or less paralleling the bedrock. These streaks may sometimes be exceptionally rich and yet be not more than one or two inches in thickness, hence missing or overlapping will give false results. It is advisable when removing the outside gravel to leave the face as smooth and even as the character of the gravel will permit, thus greatly facilitating the taking of the sample.

Sampling

When the gravel face has been satisfactorily prepared, start on bedrock and measure up one foot, putting a small wooden peg at that point, then, holding the pan on the bottom so as to catch all loosened gravel, start to remove the sample by means of a small pick, working from the bottom up to the height marked by the peg. The sample should be taken up and down the first foot section in as nearly a straight line as the formation will permit, care being taken that an equal quantity of the gravel is removed from all portions along the line of the cut. This method prevents obtaining a false result which would ensue from taking too much or too little of any rich streak that might be present. Take sufficient gravel to fill the pan evenly, allowing all rocks which may be included to remain in the pan.

The full pan of gravel is then taken to a convenient pool and carefully panned, colors being counted. Record the number of colors, position of the sample, and the estimated number of pans to the cubic yard for that particular stratum. Sample the next foot in a similar manner, continuing the work until the bank has been sampled a foot at a time. When the sampling is completed, a small cut will have been taken from top to bottom.

If the gravel in the bank is fairly uniform and is to be treated as a whole, the colors from each successive foot may be put together in a small vessel for weighing, but if on the other hand, the bank has been divided into several strata, all colors from the same stratum should be put together, each stratum being figured separately.

The calculating of results is simple. The gold obtained is carefully cleaned and weighed and its value in dollars and cents determined. This sum is then divided by the number of pans taken and the result multiplied by the estimated factor which gives the value per cubic yard for the bank. The following is an example taken from actual work. The bank in this instance was 10 ft. high, and from it 10 pans were taken. The gold recovered weighed 30.4 mg. with value for this locality of 1.76c. or 0.176c. per pan. I estimated 70 pans to the cubic yard, giving a bank value of 12.3c. per cubic yard. The following may be given as another example in which it was found necessary to sample the separate strata owing to a very considerable difference in the character of the gravel. Height of bank 35 ft. divided into two strata of 14 and 21 ft. in thickness; for the 14-ft. stratum 40 pans to the cubic yard was allowed and 70 for the 21-ft. stratum; weight of gold obtained from the 14-ft. stratum 160 mg. with value of 9.25c.; fourteen pans were taken giving a value of 0.66c. per pan to which, applying the estimated factor of 40, gave a stratum value of 26.4c. per cubic yard. For the 21-ft. stratum the gold recovered weighed 64 mg. with value of 3.7c., giving a pan value of 0.18c., multiplying this by 70 gave a value of 12.6c. per cubic yard for the stratum. Now, to obtain a correct bank value the above results are averaged taking into account value and thickness of strata as follows:

$$14 \times 0.264 = 3.696$$
$$21 \times 0.126 = 2.646$$

$$35 \qquad 6.342$$

$6.342 \div 35 = 18.12$c. per cubic yard, value of the bank from top to bottom.

This method of testing, while rough, if carefully done will give fairly accurate results, as evidenced by the following: On one occasion I sampled a 17-ft. bank by the above pan method, obtaining a value for the gravel of 6.5c. per cubic yard. A few days later this same bank was tested with a carefully measured cut from top to bottom, washing, by means of a rocker 127.8 cu. ft. of gravel (measured in place) from which was obtained a result of 6.6c. per cubic yard. On several other occasions where I have checked my testing, results have been obtained which checked within one or two cents, showing that a fair degree of reliance may be placed on this method of preliminary sampling.

Advantages of Pan Testing

Pan testing is particularly useful in that it tends greatly to reduce the time and expense necessary for making a preliminary examination of an extensive territory. It enables an engineer to eliminate quickly those areas which are of too low grade to be considered. The saving in expense alone makes this method worthy of special consideration. I found, in the tropics, that with an assistant and possibly a native to carry pick and shovel, I could go over and test an extensive area of gravel in a single day, determining what parts should be abandoned and picking out those worthy of a more thorough examination. Often it would be found that whole areas did not deserve a second visit. To prospect this same area by one of the more elaborate methods would necessitate the transporting of rockers, tools, and other paraphernalia to the scene of the work, the employing of from five to ten natives with one or two extra white men to make the cuts and run the rockers, besides consuming from five to ten days in the performance of the work. The result of all such labor, time, and expense would merely prove that the gravel was not of sufficient value to warrant consideration. It is needless to demonstrate further the saving in dollars and cents that may be effected by

a thorough knowledge of the pan method of preliminary sampling.

Among the more thorough and reliable methods of testing, the next in order is somewhat analogous to the pan method, though considerably more exact in its results. It is that of measured cuts. Under ordinary conditions, if carefully done, this method is probably the most trustworthy, giving results as accurate as those obtained from actual placer operations. By this method the gold contained in a known volume of gravel, measured in place, is ascertained by careful washing. There are no uncertain factors to determine or estimate, such as the expansion in volume of gravel out of place, and by reason of the fact that the figures for gold obtained are based upon the gravel deposit, *in situ*, dependable results are by no means so difficult to reach.

Accuracy of the Method

The degree of accuracy is commensurate with the size of the sample, yet judgment must be used to keep the volume of the sample in proportion to the size of the bank exposure, with due regard also to the item of expense. Beyond certain limits, the results from an excessively large sample may not be more accurate than from one of smaller proportions, while to handle the larger sample will entail considerably more expense. The size of the sample to be taken will also greatly depend upon the character and distribution of the gold content. The average assay of a gravel deposit in which the gold is fine and evenly distributed throughout, may be determined by a much smaller sample than one in which the gold occurs as nuggets which are perhaps widely disseminated. When there is a reasonable doubt as to the volume of sample to be taken, it is far better for the examining engineer to take the sample too large than to run the risk of obtaining false results by taking too small a sample.

The volume having been determined, the bank is cleaned off from top to bottom as in the method of pan sampling, a sufficient width being taken to leave a foot on either side of the proposed cut. The gravel is then removed for washing. Too much care cannot be taken in picking out the sample in order to keep the cut of uniform size and to prevent caving or breaking of its sides. If the gravel is fairly compact and homogeneous, little trouble will be experienced. If, on the other hand, the gravel is loose, sandy, and interspersed with large sized rocks having a tendency to loosen easily and fall out, some difficulty may be encountered.

Assuming that the bank to be sampled is 35 ft. in height and that it has been decided to take a cut from top to bottom 2 ft. in width and 1.5 ft. in depth, begin on bedrock picking out the gravel, working from the centre of the cut toward both edges, but not approaching to within more than 2 or 3 in. of the final width and depth. This work may be done rapidly. When a considerable quantity of the gravel has been removed begin with great care trimming. Little by little the gravel is removed until the exact two feet in width has been obtained with a depth into the bank of 18 inches. For accurate work it will be found advisable to make a templet from a piece of board. This, in the hands of a careful workman, will give very good results. Sometimes in removing gravel a large sized boulder extending partly into the cut may be encountered, a portion of it being firmly imbedded in the surrounding gravel. To remove this boulder would probably bring into the sample a quantity of excess gravel. In such cases, it is advisable to pick carefully around the part projecting into the cut and allow it to remain, because, as can be readily seen, this will not in any way affect the results of the test. In this manner proceed to the top, at all times keeping the depth of the cut exactly 18 inches. If the bank is higher than can be easily reached, a ladder or rope may be used to work from. When taking samples from a high bank it will be found advisable to use a canvas sheet spread at the bottom, as the gravel dropping from such a height will have a tendency to scatter. Often it is a good plan to use two pieces of canvas, one at the bottom and the other hung on the face of the bank over the cut. This precaution confines the loose gravel to the cut and it will drop to the bottom as through a pipe or shoot.

In some cases owing to configuration of the bank, it may be impossible to make a continuous cut from top to bottom in which event it can be taken in sections; care being used, as previously mentioned, not to omit or overlap any portion of the bank.

The gravel as removed is carefully washed by means of a rocker. When all gravel has been washed and the cut carefully checked as regards accuracy of measurements, the recovered gold is cleaned, weighed, and the gravel value calculated, as follows:

Cut $1.5 \times 2 \times 35 = 105$ cu. ft.

$105 : 27 :: 20.7 : X.$

$X = 5.3$c. per cu. yd., bank value.

Results by this method are as reliable as any that can be obtained, if work has been carefully and scientifically done. A deposit of gravel tested by a sufficient number of these cuts so as to obtain a fair average can be relied upon to yield results that will check very closely with those obtained by actual mining operations.

Deposits Suitable to this Method

The particular method of testing described above is only applicable to such deposits as have a fairly perpendicular bank exposure from bedrock to grass roots such as may be found on the stream side of bench deposits. Where no such exposures exist, resort must be had to another form of the measured cut system—that of shaft sinking. Where accurate results are desired, this method is limited to such areas as have little or no bedrock water. To sink a shaft where from two to three feet of water may be encountered on bedrock and to obtain results that will even approximate true conditions, is almost a physical impossibility: therefore,

when this condition exists, other methods which will be considered later should be adopted.

When testing by means of shafts, one of two systems may be used. The shaft may be sunk to bedrock, keeping it to an accurately measured size and washing all the gravel obtained; or, the shaft may be sunk to bedrock and made of such size that it can easily be worked in. When bedrock is reached, measured cuts can be taken from top to bottom in the sides. If all the gravel is to be washed, it is customary to sink the shaft of such dimensions that every three feet in depth will represent a cubic yard in place. Circular shafts should have a diameter of 3 ft. 5 in., while rectangular shafts are made 2 ft. 3 in. by 4 ft.; both of these sizes, while small, are sufficiently large for an experienced shaft man. Of the two styles, I prefer the circular shaft, as the gravel will stand better and there is less trouble from caving. Where timbering has to be done, the rectangular shape will, however, be found preferable. For the circular shaft, a templet made by nailing together in the form of a cross, two pieces of wood measuring 3.4 ft. in length is convenient. This templet may be suspended from the centre by a cord and can be raised or lowered in the shaft, thus keeping the shaft of a uniform size as sinking progresses. Care must be taken not to gouge the sides, but the shaft should be kept as symmetrical as possible at all times. When bedrock has been reached, it should be thoroughly and carefully cleaned. It is good practice to sink a foot or two into the bedrock in order to make sure that all gold has been recovered. All gravel as removed is carefully washed in a rocker. The washing should be kept abreast of the sinking in order that, by observing the returns, the depth and position of pay-streaks may be noted. The recovered gold is cleaned, weighed, and results figured. The depth of the shaft gives the yardage contained in the sample.

Prospect Shafts

When cuts are to be taken down the sides, make the shaft of such size that it will permit of rapid sinking. For this method the rectangular shape will be found more convenient than the circular. After the shaft has reached bedrock, carefully remove all loose material and pick down the sample from one of the sides or ends, keeping the cut to exact dimensions as previously described. The sample is hoisted out by bucket and carefully washed, the value per cubic yard being determined as already described. If the testing is to be thorough, two cuts may be taken, one from either end, or one from a side and one from an end, or any such combination as the man in charge may elect. The work of taking the cut can be greatly facilitated if, when sinking the shaft, care is taken to keep the side or end from which sample is to be taken as true and uniform as possible.

Of the two methods, that of washing all the gravel removed, is the more reliable, owing to the larger volume of the sample and the proportionate reduction in error due to possible loss of gold. Against this, however, must be considered the increase in time and expense incident to the handling of a greater volume of gravel. Furthermore, if the gravel has a tendency to loosen and cave, it is sometimes impossible to pick an accurate cut down the sides; often a circular shaft, if quickly sunk, will stand sufficiently long to reach bedrock and obtain the complete sample. In recent testing, in a somewhat loose and sandy gravel, I found in every case that a fairly uniform circular shaft could be sunk to bedrock and a complete sample obtained where my attempt to take a cut in the sides resulted in extensive caving and the ultimate loss of the shaft.

Another form of testing which should be properly classed under the head of measured cuts, is that of bedrock driving. This is applicable to bench deposits where it has been determined that all gold lies in the foot or two of gravel resting on bedrock. To prospect such a deposit across the full width of the bench by pits, would entail the sinking of several very deep and expensive shafts, while much more reliable results can be obtained at much less expense by driving on bedrock. Care should be taken in all such cases to have the drift at right angles to the line of flow, otherwise erroneous results will be obtained. As samples of this nature are necessarily large in volume, the same degree of care in washing and handling is not required as for those of lesser volume. To save time, the gravel may be washed by means of a small and carefully constructed series of sluice-boxes, the boxes being of sufficient length to ensure complete recovery. This method very closely approximates actual operating conditions. In obtaining results by this method, it is the general practice to base figures upon the value of gold recovered per square yard of bedrock uncovered, from which, when the average height of gravel on bedrock along the line of the drift has been determined, the value per cubic yard is computed. The one measurement to be watched in this work is the width of the drift. This should be uniform and great care should be taken not to gouge into the sides and thus obtain an excess of the rich pay-streak.

The following case, from my experience, will serve as an example of the above method. There was a bench deposit which on the stream edge measured 24 ft. in height, increasing rapidly but uniformly to 39 ft. on the inside. The gold lay in a streak on bedrock varying from 18 to 24 in. thick, everything above this streak being practically barren. It was obvious that the most accurate and the quickest way of testing this deposit was by means of a bedrock drift at right angles to the line of flow. A drift of uniform width (4.5 ft.) was maintained and all gravel removed was washed through sluice boxes which were cleaned up every evening. After driving 52.5 ft. the other rim of the bench was reached. From this drift gold to the value of $131.40 was obtained and 26.25 sq. yd. of bedrock uncovered, which yielded assays of approximately $5 per sq. yd. of bedrock cleaned. By survey over the line of the drift, I found the average depth to be 10.3 yd., which gave a value to the gravel in the deposit of 48.5c. per cubic yard.

For such gravel areas as are swampy, or that contain underground water, or in which the gravel is too fine and loose to admit of shaft sinking, the before described methods are not applicable and resort must be had to mechanical means for obtaining samples. The most widely used mechanical method adapted to this kind of work is that of churn-drilling. Much has already been written regarding this method of testing gravel deposits, and the process will not be described in detail here.

Use of Power Drills

Briefly, the drill method consists of forcing a pipe or casing through the gravel to bedrock, removing the gravel from the interior as the casing descends, the removed gravel being carefully washed and gold recovered. For this work two sizes of casing are employed, of 4 and 6 in. diameter, casing of greater diameter being rarely used. The area enclosed by the cutting shoe on the end of a piece of 6-in. casing varies from about 0.196 to 0.25 of a square foot, which is equivalent approximately to the 0.000005 part of the area of an acre, an infinitesimal quantity. In the same way, the volume of gravel removed from a drill-hole is relatively very small as compared to the volume of gravel contained in an acre, which goes to show what a very small proportion of the metal contents of an acre one hole would give. Should the character of the gravel in the acre be entirely homogeneous, with gold distributed throughout every part and all particles of equal weight, then one hole to a given tract would afford an accurate determination of the gravel value for that tract, as every other hole put down would be but a repetition of the first. Such conditions unfortunately rarely, if ever, exist. A hole might descend into an almost barren region which would not, perhaps, be more than 7 or 8 inches in diameter, while the adjacent gravel would be of high grade; or, on the other hand, the pipe in its downward course might enclose within its 0.25 sq. ft. of area the only existing nugget within the whole tract. In the one case a negative result would be obtained where it should be high, while in the other case, a high result where it should be low. This brings out a point of prime importance, namely, that the value of the gravel in any given tract cannot be determined by the results from individual holes but must be based upon an average of results from many holes. I have in mind a piece of dredging ground now under operation which aptly illustrates the above. The gold in this property was coarse and nuggety, with areas of high and low value. During the dredging operation careful watch was kept to determine, as closely as conditions would permit, the degree of variation between the actual value as shown by the dredge operations and the estimated value as determined by the drill tests. It was found that this variation in a great many cases amounted to 10c. to 15c. per cubic yard as shown by individual drill holes, yet the dredge returns for the whole area gave an average value per cubic yard which approximated within 2% of the average value of the gravel as computed from the drill tests.

In a preliminary drilling it is customary to place holes in lines sometimes 500 or 1000 ft. apart with 200 or more feet between the holes. This would mean an average of two holes or less to the acre. In the final drilling, holes may be placed 50 ft. apart with a distance between lines of 200 ft. This would only make a possible 8 holes to the acre, yet such is the law of compensation that an average of all holes will give a fairly reliable idea of the gold content of the gravel. The average value shown by the eight holes to the acre would be far more accurate than that of the two to the acre. The degree of reliability of results obtained by drilling a given tract is largely dependent upon the number of holes drilled in that tract.

Besides the above, another feature greatly affects results and that is the amount of care and thought used in putting down holes. In drilling placer deposits, owing to their generally shallow nature, it is easy enough to put down a hole to bedrock, but to put that hole down in such a manner as to obtain at all times an accurate sample of gravel for every foot is quite another matter. Great care must be taken when in tight or hard driving ground, not to force or push out of the way gravel which rightfully belongs within the sample or, on the other hand, when in loose running ground, not to include gravel which does not belong in the sample. These are points which must be carefully watched and steps taken to prevent their occurrence or, if unavoidable, the excesses or discrepancies in volume noted and allowed for when final computations are made. It is here that the skill and experience of the examining engineer enters into the reliability factor.

Use of the Hand-Drill

Much consideration also must be given to the type of drill used. Some machines, because of their method of operation, naturally give more trustworthy results than others. Of the types now on the market, probably the most reliable, and one which more nearly approaches the ideal method of sampling, is the hand drill. This with its rotating cutting shoe, which bores into the gravel descending by its own weight, comes as near cutting out a true cylindrical sample of the gravel from top to bedrock as it is possible to obtain. Steam machines which depend on heavy blows to drive down the casing, with the accompanying dropping of the heavy stem, cause such a loosening and disturbance in the surrounding gravel that an increase in the volume of the sample extracted is nearly always found. However, it has been demonstrated that in a carefully drilled piece of placer gravel, the estimated gold content in dollars, as based on drill-hole results, will approximate within less than 5% of the actual bullion value as extracted by the dredge.

In conclusion, when asked the degree of reliability to be placed on any placer examination, it is necessary to first know the general characteristics of the deposit to be examined, secondly, the method of testing to be employed, and, thirdly, the care and experience of the examining engineer.

THE WATER FRONT AT KETCHIKAN, ALASKA.

Mining Revival in the Ketchikan District, Alaska

By E. E. HURJA

The Ketchikan mining district, southernmost of Alaska's mineral belts, comprises 9370 sq. mi. of territory, of which about half is represented by islands. The largest insular body is Prince of Wales island, the next is Revillagigedo island, the one with an area of 2800 and the other with 1120 sq. mi. Although prospectors, attracted by the Klondike and Juneau goldfields, have passed through the Ketchikan district for nearly two decades, no real exploration was done until about 1900. So far as known, no attempt was made to seek mineral wealth during the Russian occupation of the territory. Charles Baranovich, a Russian merchant, is reported to have prospected for copper near Kassan village soon after the American occupation of Alaska, but nothing further is known. James Bawden, still a resident of Ketchikan, discovered workable deposits of gold on the eastern side of Annette island in 1892. William Barnard found gold and copper near Kasaan village in 1893; other discoveries were made in 1893 and from 1899 to 1901 there was considerable mining activity. Many hundreds of claims were staked. Ketchikan is the supply centre for the entire district. It is situated on the west side of Revillagigedo island and on the east side of Tongass Narrows. It is 660 miles northwest of Seattle and 240 miles southeast of Juneau. Salmon canneries, sawmills, fertilizer factories and other minor industries supplement mining. It has a number of stores, is a port of entry, and has a population of about 1500.

Copper in the Ketchikan district occurs in irregular lenses and is mined generally by following the orebody. The bulk of the copper ore is chalcopyrite and cupriferous pyrite, accompanied by magnetite, pyrrhotite, and other sulphide minerals. Development has been slow and there are not many producing mines in the district. Abundant water-power is available on nearly every island, while the resources of hemlock, spruce, and cedar furnish ample timber for present needs.

The oldest regular producer in the district is the Jumbo property near the head of Hetta inlet, on the west coast of Prince of Wales island. It is operated by the Alaska Industrial Co., of New York, of which Charles A. Sulzer is manager. A depth of 800 ft. has been attained on the orebody, with a winze put down 200 ft. below the lowest working level, No. 4. Shipments to the Tacoma smelter are being made at the rate of 1000 tons per month. The Copper Mountain group of claims at Hetta inlet have been taken over by the Alaska Consolidated Mining & Smelting Co., of Duluth, Minnesota, and are being developed under the direction of R. L. Kilpatrick, superintendent. A smelting plant of 250 tons daily capacity has been idle since 1907. Prospecting is being done on the Red Wing group of claims, near the entrance to Hetta inlet. Small shipments of ore from the vein deposit on the Red Wing claim have been sent to the smelter at irregular intervals since 1903.

Kasaan Bay Claims

Rush & Brown, operating on a group of claims near the head of Kasaan bay, have been shipping at intervals since 1906. Regular shipments are now made at the rate of 300 tons per month. A depth of 184 ft. on the orebody has been increased by 50 ft. during the past year. Ore is being mined from both the magnetite and sulphide orebodies. A railroad 3½ miles in length con-

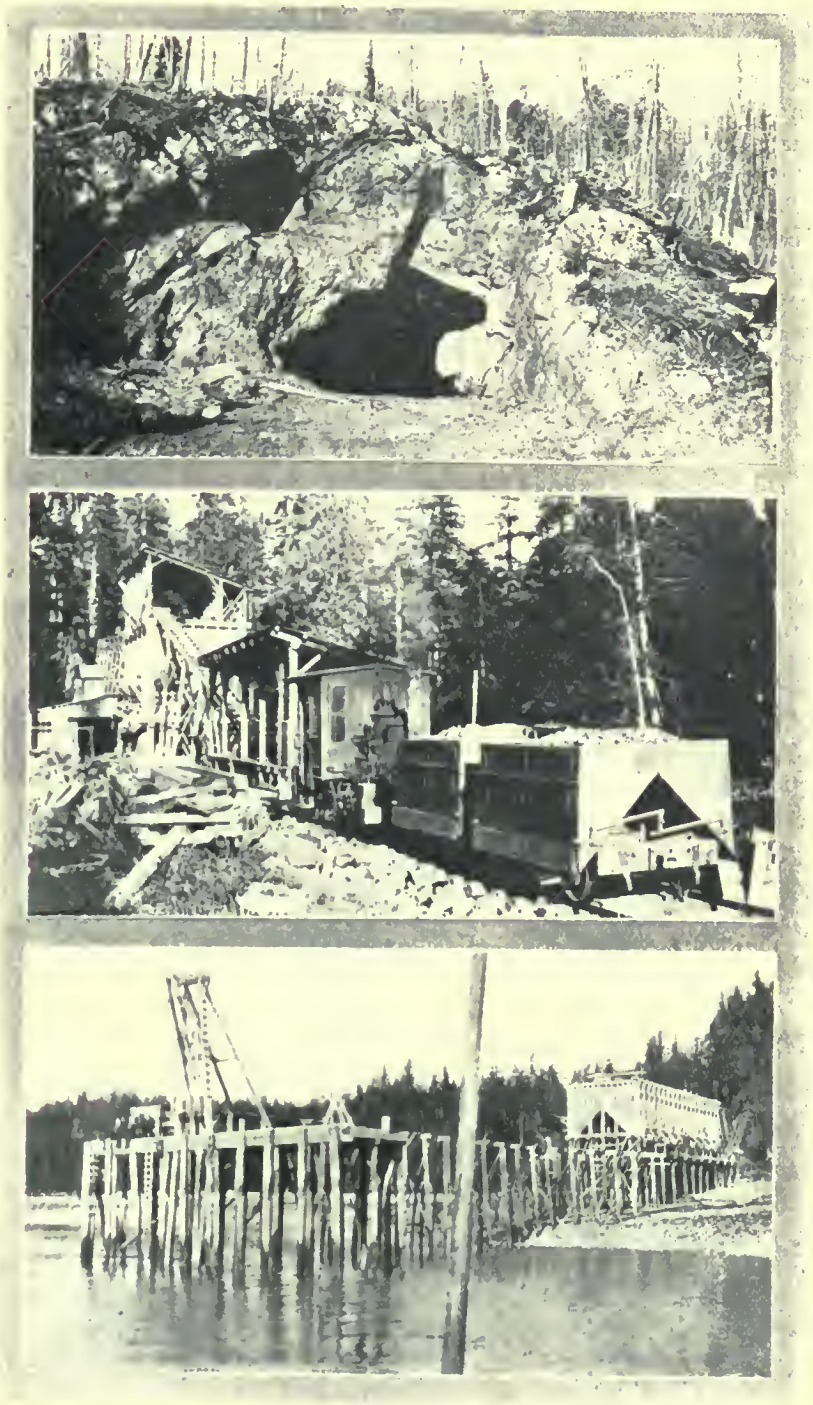
nects the mine with the ore bunkers and wharf. The Goodro claims at the head of Karta bay are being developed. Native gold and chalcopyrite occur in the bornite ore mined from this property. A shipment is being prepared now for smelting. Development work on the Mt. Andrew property, at the head of Kasaan bay, 27 miles from Ketchikan, was resumed in January, under the direction of W. J. Rogers, superintendent. The claims are being surveyed for patent. The property is owned by the Andrew estate of England and has made numerous shipments. A cable tramway 3600 ft. long connects the mine with the wharf. Six different and irregular ore masses have been opened.

Due to the advent into the Ketchikan district of the Granby Consolidated M. S. & P. Co., work will be resumed on the Mamie group on Kasaan peninsula, near Hadley, 30 miles northwest of Ketchikan. The Granby company has bought and paid for the property, and has started to place the buildings and trams in condition for a resumption of active development. A contract to explore the claims with a diamond-drill has been made. The other acquisitions of the Granby company in the Ketchikan district are the It and Dean mines, near the head of Kasaan bay, three miles from Kasaan. The It property is equipped with a steam power-plant, ore bunkers, dock, and tram. The new owners expect to start work July 1. The Dean group, adjoining the It, will be worked in conjunction with the It. Four hundred feet of development work has been done on the Dean and a depth from the surface of 80 ft. attained.

The Valparaiso Claims

Plans to resume work on a large scale on the Valparaiso group of claims, a mile and a half from Dolomi, and owned by the Princeton M. & M. Co., have been completed and are being carried out under B. A. Eardley, manager. On June 11, fifteen tons of machinery left Ketchikan for the property. Work on the claims was discontinued in the fall of 1913 because of water; but during the winter a 600-ft. drainage adit was driven, so the mine again is unwatered. A five-drill water-operated compressor will be used in supplying ore for the 10-stamp mill, which is operated in connection with a Chilean mill, giving a capacity of 50 tons per day. The ore is a gold-bearing quartz in a fissure vein.

The Alaska Venture Syndicate, Ltd., of London, a subsidiary of the Great Boulder Proprietory of Australia, has acquired the Old Glory group of claims on Smuggler's cove, Cleveland peninsula, 25 miles north of Ketchikan, from Martin Bugge and associates. The final payment was made in February. J. T. Hollow, of London, engineer for the Company, is now at Ketchikan, preparing to install the prospecting plant on the claims. The improvements include a three-drill com-



1. ENTRANCE TO RUSH AND BROWN MINE.
2. MINE TERMINAL OF RUSH AND BROWN RAILROAD.
3. RAILROAD TERMINAL AT HEAD OF KASAAN BAY, PRINCE OF WALES ISLAND.

pressor and a dam for the power-plant. Forty thousand dollars has been allotted by the Company for preliminary prospecting. Work has been resumed 1000 ft. below the old adit. Fifteen hundred feet of adit has been driven and two small low-grade orebodies have been cut. The adit will be continued 600 ft., to cut the main orebody. E. T. Leahy is superintendent for the Company. The ore is free-milling. The Alaska Venture Syndicate has taken an option on the Goldstream mine on Gravina island, three miles from Ketchikan, and is preparing to resume development work on the claims. Owing to a lack of funds, the Moonshine silver-lead property, on Cholmondeley sound, owned by the Sunshine Mining Co., is idle. One hundred and fifty tons of ore is on the dump awaiting shipment.

A thorough sampling and examination of the Julia group and Humboldt claims, on 12-Mile arm of Kasaan bay, 40 miles from Ketchikan, has been made by engineers of the Alaska-Gastineau company. The property is owned by M. K. and J. H. Rodgers and has been operated for a year and a half under bond and lease by M. M. Reese and H. Webber. The vein is from two to 12 ft. wide. A small compressor plant and a five-stamp mill, both operated by water-power, are at work on the property. Mr. Reese is now at Juneau, conferring with the Alaska-Gastineau company officials over the possible sale of the claims.

The Crackerjack Property

The Crackerjack group of gold claims, but recently out of litigation, and which has been idle for a number of years, is being developed by the owners, James Bawden and Morris McMicken. The property is a mile north of the Julia group. The vein has a width of from 2 to 14 ft. and assays from $8 to $15 per ton. The underground development work aggregates 2864 ft. A preliminary sampling was completed last week by M. Nash, of Juneau, reported to be acting for foreign capital. Adjoining the Crackerjack is the Ready Bullion property, on which a five-stamp mill is operating. The property is owned by Webber & McKenzie. A new level has been opened up, at a depth of 170 ft. Three hundred feet of drift has been driven on the vein. Mill runs show a value of $30 per ton. The vein is narrow. The Cascade property, four miles from Hollis, has been examined by engineers and is under bond. The claims are owned by C. Radenbaugh, who has operated an arrastre and a two-stamp mill successfully on the property during the past two years. Eight miles from tidewater at Hollis, and west of the Crackerjack group, is the Lucky Nell group, owned by G. W. and Fred Gervais. Thirty tons of ore was shipped out last winter to the smelter. Forty-six dollars per ton was obtained, which netted $33 per ton after smelting and freighting charges had been paid. Adjoining the Lucky Nell group are the Commander claims, owned by Gust Detlefson. Development in a small way is being carried on.

O. Jacobsen and E. Olsby are prospecting the Bruce group of seven copper claims, four miles from Sulzer. The property has on it two 60-hp. boilers, one six-drill Rand compressor, and other machinery, as well as buildings. Since the dock collapsed in 1913 when a 300-ton shipment of ore was being loaded on a ship, nothing has been done. Wright & Reynolds, working on Nutqua lagoon on the west coast of Prince of Wales island, have a vein varying in width from two to six feet. An adit 200 ft. long has been driven and 180 ft. from the portal, a winze sunk on the vein. Work on the big adit of the Northland Development company at its copper property 10 miles from Craig is progressing. Stoping on the orebody has been started. B. Tucker is manager.

A group of seven claims is owned by Richard Nuckolls and Gundar Nygard on Revillagigedo island at Thorne arm, 25 miles from Ketchikan. Open-cut prospecting has uncovered a vein 15 to 30 ft. wide for a distance of 3000 ft. King & Gilmour are developing the Sea Level claim, one of the first in the district, on which a 30-stamp mill was erected after 50 ft. of shaft had been sunk. Development work on the Wild West group, owned by Mrs. Al. Smith, is going on. The Gold Banner claim, owned by Bert Steers, has an adit 80 ft. long which cuts a vein six feet wide. The owner is prospecting on the surface at present.

The Gold Standard was the first claim discovered in the Helm bay district, having been found in 1900 by Johnson and Dyer. It is owned by Nuckolls, J. E. Chilberg, and C. E. Ingersoll. A test shipment made last month has shown a value of $5 per ton said to represent a face 130 ft. wide. Two miles north of the Gold Standard is the King & Elliott group, recently discovered and under bond for $60,000. The group consists of four claims. Several shipments of low-grade ore have been made from the Gold Mountain group, owned by Richard Nuckolls. Three hundred feet of adit has been driven along the vein at a depth of 200 ft. The vein is 30 ft. in width. The tests show ore worth $6 per ton. Polson & Ickis have a copper and gold property on McLean arm, 40 miles from Ketchikan, known as the Veta group. Two chalcopyrite deposits have been developed for a total distance of 265 feet.

Marble Deposits

In addition to copper and gold, marble forms one of the mineral resources of the Ketchikan district. The Vermont Marble company owns a total area of 703,246 acres of land, and operates a quarry at Tokeen, near the northern end of Prince of Wales island. Edward Brown, an assayer, who has been in Ketchikan for 11 years, says he has examined specimens of chrome iron, manganese, tin, scheelite, and platinum which were brought in by prospectors from different parts of the Ketchikan mining district. The United States recorder for the Ketchikan district reports that since 1902 a total of 4250 claims have been staked in the district, of which a larger portion has lapsed. Thirty placer claims have been recorded on the Unuk river, about 60 miles from Ketchikan.

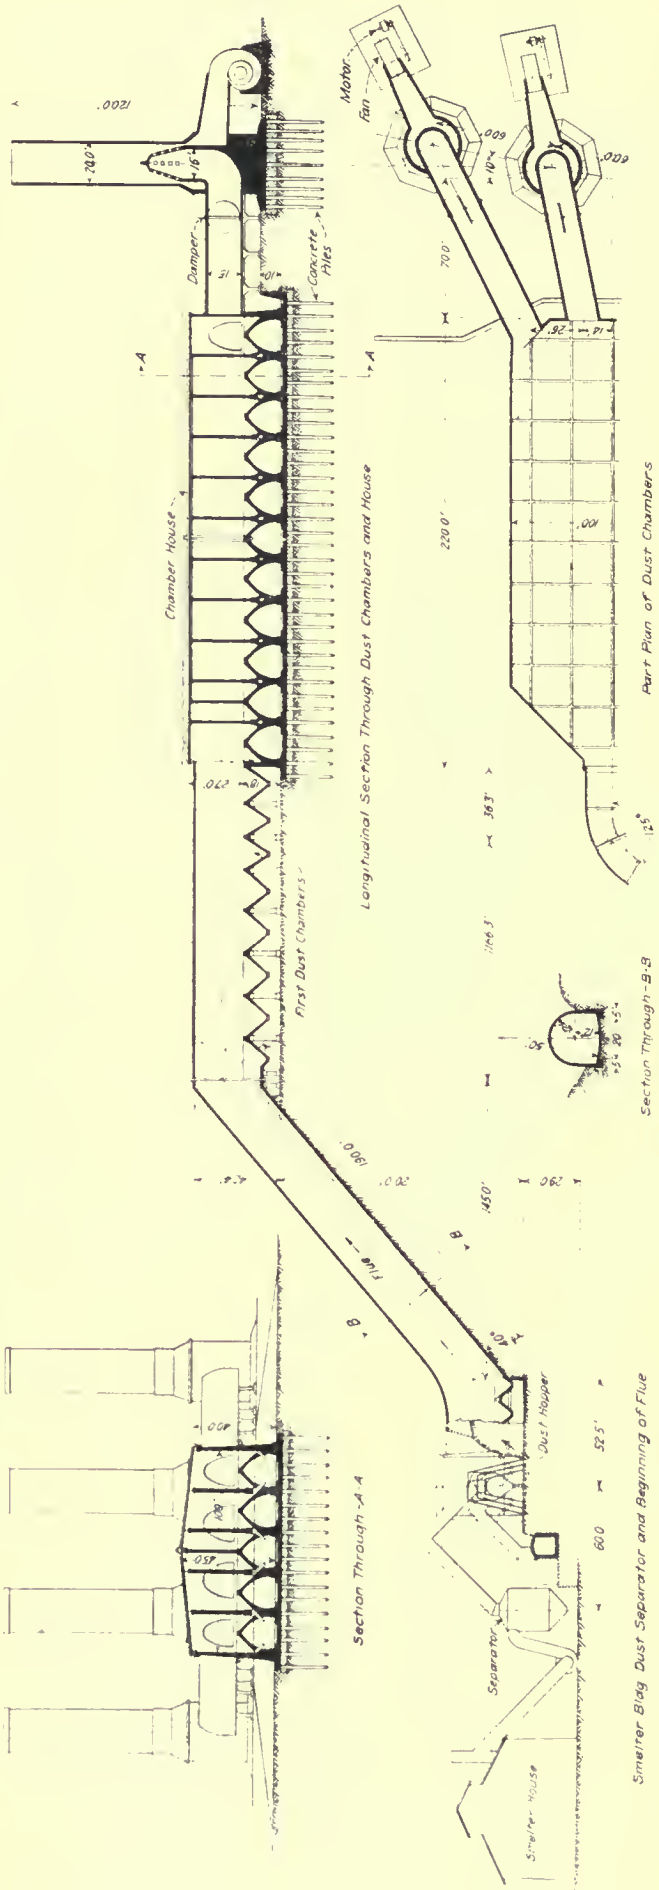
Dust Chambers at the Ashio Smelter, Japan

On June 15, 1912, the Imperial government of Japan passed a bill requiring the Japanese smelters to install equipment for the elimination of smelter dust and fume, which in many instances had become a menace to agriculture and had destroyed the vegetation in the vicinity of the smelters. This bill affected five smelters in Japan, and equipment is now being installed at the different plants to meet the requirements of this law. In the accompanying drawings there is presented two sections through the new reinforced concrete dust-chambers at the Ashio Copper Co.'s smelter and a part plan of the chamber building. This work, which is in course of construction, will probably be finished by the first of November.

At the Ashio plant there are three furnaces in operation, with an output of about 50,000 lb. of copper per day. From a charge made up of 11.5% Cu, 24.4% Fe, 23.8% S, 0.65% As, 30% SiO_2, and 7% Al_2O_3, a 94.4% extraction of the copper is obtained. The gases from the furnaces were formerly allowed to escape directly into the air, which has resulted in the killing of all vegetation within an area of one-half mile radius from the plant and permitting of but little vegetation within a mile from the plant. The volume of SO_2 escaping into the air is over 2400 cu. ft. per minute. The smelting plant is an interesting one since part precipitation of the SO_2 is effected by the use of lime water.

The flues and dust chambers are built of reinforced concrete with but little metal exposed to the action of the fumes. The gases from the furnaces pass through a dust separator as shown in the diagram. Here a spiral motion is imparted to the gases and a large per cent of the dust is deposited and drawn from the cone-shaped hopper in the bottom. From the separator the gas passes up an incline flue, in the lower end of which are several hoppers in which the dust collects. At the top of the flue the gas passes through a series of chambers before it enters the main chamber house. Up to this point and in the first few hoppers in the chamber house the dust that is collected in the hoppers will contain copper in sufficient quantity to make it of commercial importance and will be subsequently recovered. In the chamber house proper the dust will contain such a high per cent of arsenic, zinc, and other impurities that it will be of no value and will be discarded.

The chamber house is subdivided into many compartments and the gas as it passes through meets many obstacles in the shape of concrete partitions, baffles, and wires. Wires, as has come to be the common practice in the United States, will be used in these chambers for the separation of the dust from the furnace gas. The main building as shown in the diagram is 220 ft. long by 100 ft. wide. The chambers are connected with four stacks, three of which will be in constant use, the fourth being held in reserve. As the gas emerges from



the chamber room it passes through flues to the stacks, which flues end in dome shaped structures as seen in the diagram, which have numerous openings causing the gas to be disseminated and mixed with the air before passing to the open. The stacks are connected with fans as shown in the cross-section, which fan blows air into the stack around the openings from the flue, where it mixes with the escaping gases. Besides adding air to the gas before it passes into the open, it of course reduces the pressure in the chambers and forces the draft. The velocity of the gas through the chambers will be about three feet per second. Dampers are placed in the flues for the regulation of the flow of gas through the chambers. The chambers and stack are supported on concrete piles.

Eliminating the Mosquito

Effective methods of getting rid of mosquitoes can never be too generally known, and the following account by Lloyd Noland, superintendent of the health department of the Tennessee Coal, Iron & Railroad Co., Birmingham, Alabama, of the methods used by that Company, as reported in the *Bulletin* of the American Iron and Steel Institute, will be of interest.

A careful inspection of all streams, ponds, pools, and springs, both within and for a distance of one mile around each camp, was made early in the spring. *Anopheles* larvæ were found in practically all places of this character. *Culex* larvæ of several types were found in rain barrels, tin cans, fire barrels, septic tanks, collections of dirty water around houses, and even in mines at some points.

The work accomplished consists in draining and filling all pools and swamps, where practical; the weekly spraying with crude petroleum or larvacide of such pools or swamps as cannot be filled or drained; the clearing of vegetation in swampy spots; the maintenance of drainage ditches; and the installation of automatic oil drips at the head of sluggish streams. All rain-barrels are destroyed or removed; tin cans and bottles are carefully removed from all parts of the camp; and larvacide, manufactured by the Company, is added to water in fire barrels. General screening of all houses, while ideal as a protection, is too expensive to be considered. Screening has been resorted to only as a protection against mosquito infection in houses where there are actually cases of malaria.

Filling and draining of swamps and pools is by far the most logical and economical method of destroying these breeding places. The first cost of such work may be a considerable item, but this is more than balanced when the yearly cost of oiling is considered. Oiling has been accomplished by the use of drip barrels or larvacide. The first, a closed barrel, containing 10 to 15 gal. of ordinary crude petroleum, is equipped with an ordinary ⅜-in. gate valve and mounted on a small platform at the head of such sluggish streams as are found to contain larvæ. The valve is cracked sufficiently to allow a regular drip, rapid enough to give a light film on all water running through the ditch. A surprisingly small amount of oil is required for this purpose. It is necessary with such streams to straighten the banks to remove obstructions such as trash, grass, etc., that may hold back the descending film. Very little work is required to keep these drip barrels in operation, a weekly inspection and refilling being about all that is necessary.

In the second method, isolated pools are sprayed with oil or larvacide, as the case may be. There are many sprays on the market of the knapsack type that answer excellently for this purpose. Pools of large size that are exposed to the action of the wind and that contain much vegetation are difficult to handle because of the fact that the oil film is frequently blown entirely away from a large part of the pool. In order to handle situations of this kind properly, a larvacide developed at Panama is used. This larvacide we manufacture in the following way: One hundred and fifty gallons of crude carbolic acid is heated in an iron tank having a steam coil at 50 lb. pressure. Two hundred pounds of finely crushed and sifted common rosin is dissolved in the heated acid, and 30 lb. of caustic soda dissolved in 6 gal. of water is added. A mechanical stirring rod attached to the tank is used constantly during the process. The product is prepared in a very few minutes, yielding about three and one-half barrels of larvacide, the cost being approximately 19c. per gallon.

A dilution of larvacide of one to ten thousand is amply sufficient to kill all larvæ in pools; a certain amount of care, however, has to be exercised, as this material is somewhat poisonous to stock and will quickly kill fish. Inspectors are required to have sufficient knowledge of mosquito larvæ and of adult mosquitoes to differentiate types. Careful inspection is insisted upon, and complaints of householders of the presence of mosquitoes is investigated. The work already done has shown surprisingly good results, the number of cases of malaria being enormously reduced and the comfort of the people greatly increased.

The following accounts of actual results attained, reported in the *Bulletin*, are encouraging. W. G. Kranz, manager for the National Malleable Castings Co., Sharon, Pennsylvania, reports that the greater portion of the Shenango valley at one time was swampy and malaria was very prevalent; but in recent years, as a result of the industrial development, the lowlands have been filled in and malaria has disappeared almost entirely. Walter Wood, managing director of R. D. Wood & Co., Philadelphia, Pennsylvania, states that in the ordinary development of the land around that plant they have naturally and properly made a point of filling in all low spots. This has been so efficacious that the report comes from the Camden Works that "our wharf watchmen and various boat captains at the wharf state that they are not bothered at all" by mosquitoes. Many other successes of this nature have been reported from other parts of the country.

Australian Jam and the Malay Tin Industry

The recent arrival in San Francisco of Henry Jones, a well known jam manufacturer and mining man from Tasmania, brings to mind the relations of fruit canning to tin mining. The following notes, prepared mostly from a recent issue of *The Daily Telegraph*, Sydney, New South Wales, show how close the relation is. In the November and December issues of *The Mining Magazine*, notes were published on how experience in the banana trade of Fiji qualifies anybody for the management of a copper company. The editor of *The Mining Magazine* could not see any relation, although a correspondent thought he could. In the case of jam and tin brilliant results in tin mining have followed the incursion of jam manufacturers into the Malay States.

The world's production of tin in 1913 was 119,000 long tons, of which 62,500 tons was from the Malay Peninsula, 24,850 tons from Bolivia, 17,000 tons from Banca and Billiton (Dutch East Indies), 5800 tons from Cornwall, 3200 tons each from Australia and South Africa, and 2450 tons from China. This is recovered mostly from placers in the Orient, from lodes in Bolivia, Cornwall, and South Africa, and by lode mining, and by hydraulicking, and dredging in Australia. Although tin production in the United States is negligible, yet this country consumed 45,551 tons of the metal in 1913, equal to about 38% of the world's output. This is used mostly in the manufacture of so-called tin plate, which consists of from 2 to 2.5% tin, the remainder being sheet steel, and is used for making cans for jams, preserves, fruit, salmon, and other foods. The average price of tin in New York in 1913 was 44.32c. per pound.

The I. X. L. Syndicate

Nearly ten years ago E. T. Miles went to the Federated Malay States with a commission to sell Australian jam, fruit, timber, and even old steamships, when buyers were offering. He had a little tin-mining experience in Tasmania, and the Chinese who owned the Eastern Shipping Co. are said to have attracted his attention to the tin deposits of Tongkah harbor. Convinced of the suitability of the locality for bucket-dredging, and satisfied of the profitable character of the ground, he returned to Tasmania with the idea of forming a tin-dredging company among local capitalists. Messrs. Jones and Peacock, two well known Tasmanian jam manufacturers, heard the returned traveler's tale, and were convinced. The high price of tin was the very bugbear of their existence as jam manufacturers, and they willingly found support for what came to be known as the I.X.L. Syndicate, taking the trade-name of the Jones jam factory products. The jam people are said to have actually found all the original capital. In November, 1906, the Tongkah Harbor Tin Dredging Co., N. L., was registered in Tasmania, with headquarters at Hobart. Its location is still jealously guarded there by the island capitalists who thus dared to pioneer what has become, or is rapidly becoming, a great industry. The Tongkah Harbor is now a company of £150,000 capital, in £1 shares, all fully paid. A first dividend of 1s. was paid in August 1909, three (amounting to 5s.) in 1911, four (9s.) in 1912, and quarterly dividends of 2s. ever since. Six dredges are at work, and another under construction.

THE MALAY PENINSULA.

All were paid for out of profits. The latter amounted to £78,304 in 1912, and to £80,024 in 1913. Put another way, the Company has returned its shareholders 28s. per share to date, or £217,500; and the market value of the shares is still today about 41s.6d. each.

Melbourne jam men, including A. W. Palfreyman, could not afford to let their Hobart rivals scoop up all the tin. With a certain amount of assistance from Sydney capitalists, they formed Tongkah Compound, N.L., registering the Company in Victoria in 1910. The

capital authorized, and issued, is £50,000, in £1 fully paid shares. The first dividend was paid in June, 1912, and regular distributions have followed since. The twenty-fourth was paid in May. Shareholders have received 49s. per share, or £122,500 in profits; and the Company's shares are still worth 66s., or well over three times their par value, upon the open market.

Small wonder that Sydney mining men declined to leave the exploitation of this wonderful profit-producing Malaya tin country to their Hobart and Melbourne friends. And it was only in accord with the earlier chapters that H. E. Pratten, a representative Sydney jam man, should pioneer Sydney operations. Mr. Pratten was one of the lucky original shareholders in the Tongkah Compound, and, realizing the potentialities of Malaya in the direction of bucket-dredging for tin, he stayed there a few weeks en route to England, in 1911. Becoming interested, he returned there again in 1912, having, prior to his departure from Sydney, formed the Austral Malay Tin, Limited, with a nominal capital of £50,000, £20,000 of which has been called up, and the £1 shares in which are today quoted at 90s. The result of that English trip was the successful flotation of the Kamunting Tin Dredging, Limited (London), with a paid-up capital of £130,000; Kampong Kamunting Tin Dredging, Limited (Sydney), capital paid up £130,000; Larut Tin Dredging, Limited (Sydney), capital paid up £50,000. Mr. Patten is president of the New South Wales Chamber of Manufactures.

Dredging at Gnow

But meantime events had been moving on the Malay Peninsula. Away up north in Siam, at a place called Renong, the English administrator of the Mines Department for Western Siam had been approached by English capitalists with a view to obtaining suitable dredging ground. He took up an area at Gnow, 10 miles south from Renong, where a dredge with 7-cu. ft. buckets started work for the Siamese Tin Dredging Syndicate about 1909. That dredge has won up to 60 tons of black tin per month, and held the record for production until last year, when the Tongkah Compound started its big returns. The Company is now erecting two dredges with 15-ft. buckets at a cost of £30,000 each.

Following the example of the Siamese Tin Dredging Syndicate, another British company, Scotch people being largely interested, sent out a representative, who acquired other areas near Renong. They built their first dredge there in 1910, and while paying their shareholders 20% per annum they have also made sufficient money to buy two large dredges, which are in commission now.

The Malayan Tin was the next English (London registered) bucket-dredging company of importance to start operations. It acquired ground which the natives had already worked in Kinta valley, near Ipoh, capital of the Federated Malay States. One dredge started in 1912, and a second was recently put into commission. The nature of the country in Kinta valley is entirely different from that of the more northerly areas. It is limestone country, and it remains to be seen whether bucket-dredging can be carried out successfully on the uneven botto uncommon to such formations. So far, the first dredge operated by the Company is doing fairly well.

Dredging in Siam

Australian associations were not nearly finished with the establishment of the Tongkah and Austral-Malay mining groups. Mr. Miles retired from his Tongkah associations, and struck out north in Siam during 1912. He had no difficulty in securing backers upon that occasion, and, selecting concessions to the north of Renong, established the Deebook Dredging, Ltd., and Katoo Deebook companies. They each have a capital of £100,000 in £1 shares. The Deebook has issued 52,000 fully paid shares, and 38,000, now paid to 19s., holding 10,000 in reserve. The Katoo Deebook has issued 43,000 fully paid and 42,000 paid to 13s. The directors are worth noting as showing how the native element is alive to the importance of the new mining development in its midst. The directors are: E. T. Miles, A. W. Palfreyman, Khan Joo Chie (Penang), A. Temple Miles, and Khan Joo Tok (Penang). Khan is practically the native equivalent of mister or gentleman, and Joo indicates a member of the native ruling family.

Among the last, but by no means least, of the Australian-controlled companies stands the Malaya Tin Corporation. Like its Sydney forerunner, Austral-Malay Tin, Ltd., it was organized to promote the flotation of sub-concerns, rather than the working of mining areas. Originally the Malay Peninsula Syndicate was formed early in 1913 at the instigation of a visitor from Siam, who offered to introduce suitably any representative man who went back with him, with a view to obtaining desirable concessions. Ultimately, T. H. Martyn, a prominent member of the Sydney Stock Exchange, whose active association with Australian dredging companies is well and widely known, was induced to undertake the expedition. He personally visited Siam and Burma, and secured valuable interests in both countries. Some of these areas have been prospected with success, while one in particular, situated in the Renong valley, 10 miles south of the Siamese Tin Syndicate leases, is said to have been proved to carry over 2 lb. of tin per cubic yard. According to official reports, about 150 acres of that lease, known as the Basin property, have already been developed, and operations are being continued on an extensive scale with boring plants over the rest of the area. The Ratrut organization is a matter of the present time; but it is not a matter of flotation, at least, in the ordinary sense of the word. Holders of shares in the Malay Tin Corporation are entitled to a preferential allotment of shares in the new Company, five for one, *pro rata* to their present holding. The £5 shares of the Corporation, it has a nominal capital of £42,000 in 8400 fully paid shares of £5 each, were quoted on April 28 at £12.

Other Australian concerns interested in Malaya, and worthy of more or less attention, include a Sydney venture known as the Kulim-Malayan Tin Syndicate, £10,000 in 1000 shares of £10 each, and a Melbourne company known as the Trong Tin Mining Co. The former is situated in the Malay state of Kedah, while the latter holds property about 25 miles south of the Larut, near the town of Brnas. The Trong has a capital of £80,000 in £1 shares, of which 30,000 were issued fully paid to the vendors, and 30,000 to subscribers at 5s. paid, leaving 20,000 in reserve.

But, as *The Daily Telegraph* says, all is not gold that glitters. Many Australian syndicates have sent representatives to Malaya, and in not a few instances the results so far have not been satisfactory for shareholders. There are, for instance, such Victorian concerns as Sungei Raia, Salak South, North Tambun, and the Hindu Chong mines. And there are others, not nearly all Victorian. The 'wild-cat' is always present when mining successes have been achieved. It is for prudent investors to weigh every statement made, and, above all, rely rather upon the reputation of the promoters than the statements made by mining nonentities.

New Dredges

A contract for the construction and erection of two large bucket dredges, at a total cost of £40,000, for equipping the property of the Kampong Kauranting Tin Dredging Co., mentioned above, has been placed in Melbourne. The specifications and design are the work of J. S. Henry, and the dredges contracted for will, it is officially stated, be easily the largest ever built in Australia. The material and workmanship will be as far as possible Australian. The latest improvements found necessary as a result of tin-dredging experience in Malaya, including the most recent type of revolving screen, will be fitted in these dredges. Large tin-saving tables are another feature, the pontoon being specially large, namely, 130 by 44 ft. by 8½ ft. deep to carry them. The boats will be fitted with close-connected 6-cu. ft. buckets, which will have a theoretical capacity of 35,000 yd. per week for each dredge, and effective capacity of 20,000 to 25,000 yd. of tin-bearing material per week. The plant specified is designed to dredge 45 ft. below water-level. The main engine is of 120 hp., and the pump installed for sluicing has a delivery of 6000 gal. of water per minute. The cost of the two dredges erected and in good working order at the property, together with the spares, tools, tin dressing sheds, and buildings, will exceed £40,000. The total weight of the dredges, with machinery, will be over 625 tons, which is considerably over 100 tons heavier than the largest dredge yet sent from Australia to the Orient. The contract time for delivery for the first dredge is eight months, and for the second eleven months from the date of signing the contract.

All tin recovered in the Malay States is smelted at Penang and Singapore. An export duty of 12.5% is levied on the tin leaving the country, and in 1912 the Government, under British control, received duty amounting to about £1,300,000.

From the above notes it must not be inferred that Australians are not paying attention to their own tin properties, as is shown by the work in sluicing at Briseis, and lode mining at the Anchor, Pioneer, Mt. Bischoff, and others in Tasmania, lode mining in Queensland, dredging in New South Wales, and lode mining in Western Australia.

Mining in the Argentine

Mining has made but little progress in Argentina. While copper, lead, silver, gold, wolfram ores, and borax salts, as well as small quantities of other minerals, are scattered over the Provinces of Mendoza, San Juan, La Rioja, Catamarca, Salta, Jujuy, Tucuman, Cordoba, and San Luis in the northern consular district, great distance from the coast and difficulty and expense of transporting supplies and ore make mining in most instances unprofitable. According to official information obtained from the Bureau of Mines at Buenos Aires, there are three copper, one borax, one wolfram, one silver, one onyx, one lime and cement, and a petroleum company now operating in this district. Two of the copper mining companies, the Famatina Development Corporation, Ltd., province of La Rioja, and the Compañia Minera Nueva Concordia, Territory of Los Andes, failed recently. From reliable private information it appears that the only mining venture conducted on any considerable scale at present in this district is the Hansa Sociedad de Minas, which works valuable wolfram deposits in the Province of San Luis. According to official statistics supplied by the Bureau of Mines, the following quantities, in metric tons, of ore were exported in 1913: onyx, 281; gypsum, 174; mica, 6; borate of lime, 958; wolfram, 536; copper, 310; and lead, 7 tons. These figures may be taken as indicative of production, as there is no ore reduction in the country. Practically all of the ore exported is mined in the northern consular district. The Sierra de Cordoba possesses rich stone deposits, the more valuable because of the small quantity in many parts of the country in building materials. According to official statistics, 11 different companies are now exploiting quarries, principally granite and limestone, in the province of Cordoba, in addition to other smaller concerns.—*Daily Consular Report.*

Indian Coal Output

The chief inspector of mines in India reports the output of coal in British India during 1913 as 15,486,318 tons from the following districts: Bengal, 4,649,852; Behar and Orissa, 10,226,389; Punjab, 51,040; Assam, 270,364; Baluchistan, 52,932; Central Provinces, 235,651; and Northwest Provinces, 90 tons. In addition, 600,000 tons was imported. Exports were 3,000,000 tons, leaving about 13,000,000 tons consumed in India, of which the railways took 4,500,000 tons.

A Michigan Stoping Method

In the accompanying diagram, Fig. 1, is shown a peculiar condition which occurred in a Michigan mine. The deposit was being worked from the lower levels up, as it was discovered by a raise from lower workings, the orebody was irregular, but for the most part was 12 ft. wide and had a dip of 45°. With so shallow a dip, the stoping could be easily accomplished from one level to that above, by merely standing on the foot-wall, as is customary in mines of low dip. The slices for stoping were mined in several different ways, according to the nature of the ore. The raises were driven straight up the dip of the deposit, as shown in the lower portion of Fig. 1. But higher up in the ore-body the dip became nearly vertical, so that a miner could not stand on the foot-wall to set up his drill. It would have been possible to let a large quantity of broken ore accumulate in order to stand on while working, as is done in back stoping, dry-wall methods, etc., but the manager did not want to tie up money by keeping, as is done in back stoping, dry-wall methods, etc., to make it possible to stand on the foot-wall, the raises were no longer put in along the dip, but diagonally, as shown in the upper part of Fig. 1. It is evident that any angle of raise desired can be obtained by driving foot-wall raises across the dip of the deposit instead of at right angles with the drift. Secondary vertical raises were also used, when desired for ore-chutes, but the men stayed in the inclined raises. This brings out the point that raises, in stoping methods, are used for two purposes, for men and timber and as ore-chutes. Thus in the illustration the men stay in the diagonal raises and blast ore down either the diagonal or the right-angled raises. In some mining methods the raises for men and timber are kept in good condition and are cribbed and no ore is dumped through them, except when driving them and in cross-cutting over to an ore-chute raise at their completion.

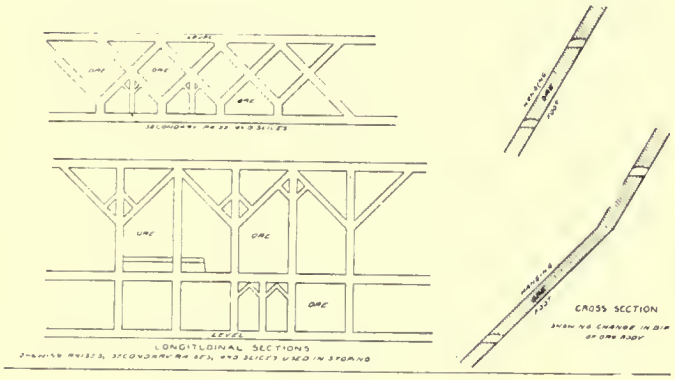


Fig. 1.

In Fig. 2 a system of raises is shown which illustrates some of the variations used in an iron mine at Negaunee, Michigan. With one-man stoper drills in soft or medium ore, raising is not expensive, and getting ore out by raises is convenient for the loading of tram cars on the level below, as ore-chutes can be constructed at the bottom of the raises. In the method shown in Fig. 2, wheelbarrows are used in the stopes for getting ore to the raises, although some of the ore falls directly into the raises, when blasted. Sub-levels and raises are popular in many of the mining methods in the Michigan iron mines for soft and medium ore.

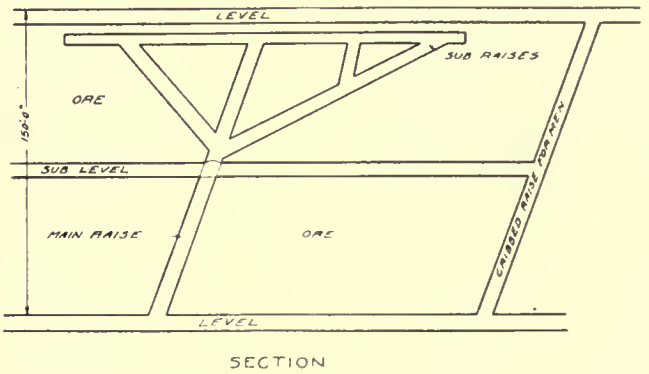

Fig. 2.

Coal Production of West Virginia

With a production in 1913 exceeding for the first time in its history a total of 70,000,000 tons, West Virginia became firmly established as the second in rank among the coal-producing states. According to Edward W. Parker, of the U. S. Geological Survey, the production in 1913 was 71,308,982 tons, showing a gain of 4,522,295 short tons, or nearly 7% over the output of 1912, up to that time the record tonnage. The increased production was accompanied by a considerably larger gain in value, which showed an increase over 1912 of $9,079,931, or 14.46%. The value of the output in 1913 was $71,872,165. The average value for the first time in ten years exceeded $1 per ton. The production increased in 1913 in spite of the facts that the labor troubles in the Paint Creek and Cabin Creek districts of the Kanawha field, which began in the early part of 1912, were not settled until well into the spring of 1913, and that the unprecedented floods in the Ohio valley in the spring reduced shipments to the west for a considerable time. A few of the mines that were closed by the strike were not reopened during 1913, and the total production from the two districts affected was much below the normal output. The increased production was well distributed over the state, there being but three counties out of thirty where decreases were shown.

According to the Bureau of Mines, the number of fatal accidents in the coal mines of West Virginia showed a decrease of 22, from 359 in 1912 to 337 in 1913, although there was an increase of nearly 10% in the number of men employed. Labor troubles caused the loss of 377,405 working days.

DISCUSSION

Readers of the Mining & Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Simplification of Gold Ore Treatment

The Editor:

Sir—Probably the most refractory 'versus' in controversial metallurgy is 'crushing in water and amalgamating *v.* crushing in solution without amalgamation.' In the *Press* of May 30, A. W. Allen cites data to prove that crushing in solution without amalgamation involves excessive precipitation with consequent fouling of solution. He instances the Dome and Hollinger mills, and probably no better opportunity has ever been afforded for comparison. As Mr. Allen points out, these mills are working side by side on ore differing essentially only in grade, the Dome crushing in water and amalgamating, while the Hollinger is crushing in solution without amalgamation. Both have been dropping 40 stamps on about the same tonnage, and both started during the summer of 1912. Mr. Allen's comparative table refers to approximate data of mill operations obtained in August 1912 while both mills were in the tuning up process, and hence should not be considered. The results during the first part of 1913 are also affected by the fact that the companies were fighting a serious labor disturbance which entailed erratic work in the mills. Hence the only figures which are of any possible value for comparisons are those from the working of the mills during the latter part of 1913 and during the present year. Accurate figures from Hollinger operations for 1913 and 1914 to date are given in the following table, and also those approximating closely the Dome present practice, as well as Mr. Allen's tabulation:

	Hollinger Mill: (Exact figures from records.)		Dome Mill: (Approximate present	As cited by Mr. Allen:	
Treatment.	1913.	1914 to date.	practice.)	Hollinger.	Dome.
Solution precipitated per ton of ore...	3.16	2.67	1.70	4.0	2.00
Zinc consumption per ton of ore.....	0.66	0.59	0.34	0.8	0.25
Cyanide consumption per ton of ore...	0.46	0.46	0.75	..	0.80
Cyanide added	Tube-mill feed.		Before agitation.	Before precipitation.	Before agitation.
Total recovery	96.10	96.00	95.00	93.0	95.00

It will be noticed that Mr. Allen's figures are sufficiently incorrect to prove his point, but that by applying his own line of reasoning to the actual figures, the exact reverse is proved, namely, that in this instance crushing in solution without amalgamation is superior to crushing in water and amalgamating.

A point of which Mr. Allen seems to lose sight is that tons of solution precipitated per ton of ore ('precipitation ratio') is a factor of the grade of ore. I quote from Mr. Allen (referring to the Esperanza): "and the amount of solution precipitated is only 3 tons per ton of ore as against twice or three times that amount in cases where ordinary stamp-milling is practised." Now at the Hollinger 2.7 to 1 is being precipitated, against 1.7 to 1 at the Dome, while the grade of the Hollinger ore milled is about three times that of the Dome. Assuming that we were amalgamating at the Hollinger and that we could make the same extraction by amalgamation that the Dome makes, our cyanide 'heads' would still be three times those of the Dome, and a precipitation ratio of 5 to 1 (3 times 1.7) would be justifiable. In other words, we would be precipitating about twice what we do now. Again assuming that the Dome ore was crushed in solution and not amalgamated, the cyanide 'heads' would be one-third of ours, so that the precipitation ratio should be one-third that of the Hollinger or 0.9 to 1. Thus the Dome is precipitating twice what would be necessary were they crushing in solution and not amalgamating.

At first sight it would look as if Mr. Allen's point is well taken, and that if the gold going into solution can be reduced, the precipitation ratio can be reduced proportionately, but actually the reverse is the case. On account of crushing in water, an excess of solution is made and a corresponding amount must be precipitated and thrown away. This precipitation of 'waste' solution added to the high-grade solution precipitation, makes the precipitation ratio greater than it would be were cyanide solution instead of water used in crushing—at the Dome twice as great. Discarding any solution from the mill other than with the tailing is poor practice if it can be avoided. One never knows whether a careless operator on night shift is not habitually opening the wrong valve and allowing good solution to get away; especially with zinc-dust a sudden loss of precipitation may run up the grade of the 'waste' solution; the cyanide loss is greatly increased and it may be necessary at any time to have to charge up a herd of sheep or a dozen cows to operation. The only point which Mr. Allen can make in favor of 'waste' solution

is that fouling is reduced, and I must say that to precipitate and throw away solution is a crude method of avoiding this difficulty. There is always a loss of solution in the tailing, so that new solution is being made all the time sufficient to offset fouling with careful operation on normally clean ore. I say most emphatically that the slogan of a good mill superintendent should be 'Not a pound of water into the mill without getting a wash with it, and not a pound of solution out of the mill except with the tailing.' If a recovery of about 80% is possible by crushing and amalgamating in water, as at the Homestake, I admit that this principle does not apply; but with only 60% as at the Dome, it does apply, and I should say that with about 63%, which Mr. Allen's figures show to be the Rand recovery by amalgamation, I would even risk a charge of heresy in hinting that it is mighty close.

NOEL CUNNINGHAM.

Timmins, Ontario, June 14.

[That it is extremely difficult to draw parallels between the practice at any two mills, it goes without saying. The innumerable factors which enter into the making of an economic ore treatment differ so widely at different properties, even in the same locality, that to state that the practice at one mill should be recognized as standard and another as deficient is misleading, even though results would seem to warrant such a statement. The discussion on 'Simplification of Ore Treatment' has been a most interesting one, in that the subject is one toward which all metallurgists are making efforts, but we believe that only a very general simplification is possible of attainment in metallurgical practice. Those details and refinements which go to make up individual efficiency will continue to depend entirely upon local conditions which cannot be changed. The questions, however, which have been raised in this discussion have been timely, and we trust may lead to a better understanding of the subject.—EDITOR.]

Platinum Assay

The Editor:

Sir—Before rational steps can be taken to conserve our platinum resources and to recover that metal from the usual run of commercial ores, it is essential to develop simple and accurate methods for the determination of the metal that may be successfully applied by general commercial assayers with the limited equipment usually at hand. I would, therefore, direct attention to certain difficulties in the three methods published by you in tabular form on page 814 of the May 16 issue.

The first method requires the use of a reagent, H_2O_2, which is not ordinarily carried by assay offices. I may also add that perhaps the limits of accuracy of this separation when considerable relative quantities of Au are to be separated from small amounts of Pt have not yet been sufficiently worked out. In the second method there are two points where great care and attention to details are required to secure anything like a clean separation. To dissolve the Ag in HNO_3 and to leave the Pt undissolved requires extremely close work, which cannot ordinarily be given in a commercial assay office, while it is practically impossible so carefully to adjust the strength of acid and temperature as completely to dissolve the Au in aqua-regia and leave the Pt unattacked. As to the third method, some tests made in the New York assay office have shown that Cd does not always prevent the solution of some of the Pt in assay buttons and this separation cannot be relied on.

Washington, D. C., May 26.

Diffusion of Ore Deposits

The Editor:

Sir—R. A. F. Penrose's valuable paper on 'Certain Phases of Superficial Diffusion of Ore Deposits' in the January number of the current volume of *Economic Geology*, recalls a matter in which I have been interested for some years. The secondary enrichment of orebodies by the downward migration of salts of the metals formed in the gossan is only one phase of a general process. From the miner's point of view it is perhaps the most important phase; but, as Mr. Penrose points out, the emphasis which has been placed upon it for practical reasons should not blind us to the more general aspect of the process. The diffusion of orebodies throughout a larger volume of rock than that in which they were formerly contained is doubtless of common occurrence. In 1910 I called attention to the diffusion of ores at a meeting of the San Francisco section of the Mining and Metallurgical Society of America.* The summary report of my remarks is as follows:

"1. The ore at Ely is a secondary deposition due to downward leaching from pre-existing orebodies at higher levels, now removed by erosion. These vanished orebodies may have been more concentrated as regards copper content than the present ores, which may be due to a process of diffusion rather than concentration.

"2. The mode of occurrence of the massive orebodies in the rhyolite of Shasta county indicates how such a derivation of the Ely ores could come about.

"3. These Shasta ores are chiefly massive bodies of pyrite with admixtures of chalcopyrite. If these, by erosion and favorable relation to the groundwater, should have come into the zone of active oxidation, the copper might well have been carried to lower levels and diffused as chalcocite and pyrite through the rhyolite, and the resulting gossan might subsequently have been removed, leaving a disseminated porphyry ore of the Ely type and no trace of the massive ore of the Shasta type."

At the Toronto meeting of the International Geological Congress, 1913, I again called attention, in the

*M. & M. S. A., *Bull.* No. 23, May 1910, pp. 263, 264.

section dealing with questions in economic geology, to the need of recognizing by an appropriate name the general process of which both secondary enrichment and diffusion are but particular phases. Another phase of the process is that which is concerned with the primary concentration of ores from the minutely disseminated particles in both sedimentary and igneous rocks, in accordance with the view held, for example, by many geologists as to the origin of the zinc-lead deposits of the Mississippi Valley. I am satisfied that many of the shallow, rich ore deposits of Nevada are due to a process of concentration from decomposing igneous rocks. The rocks from which these ores are abstracted may, in a sense, be regarded as the gossan of an extremely lean ore from which the salts of the metals are carried down by permeating waters to be deposited in favorable situations, determined by fractures, gouges, etc. The process is identical with that usually described as secondary enrichment and yet this term cannot be applied to it, since it results in primary concentration. This phase of the process realizes some of the ideas involved in the old theories of ore deposition from descending waters and by lateral secretion, but it differs from both. The important matter, as it seems to me, is that we should regard secondary enrichment, diffusion, and certain primary concentrations of ore, as phases of a general process the importance of which has not yet been fully recognized in economic geology.

ANDREW C. LAWSON.

Berkeley, California, June 23.

Revision of the Mining Law

The Editor:

Sir—Regarding the question of the 'Revision of the Mining Law,' I think it would be well for the mining world to first analyze our present mining laws thoroughly and find out why they are inefficient. The present claim of 600 by 1500 ft. is just as good as a claim would be if it was 660 by 1320. I think a claim following the dip of the vein is better than one with perpendicular lines in so far as it has a tendency to keep a miner from locating unnecessary surface land with no outcrops. But in revising a law that would make vertical lines, let it apply only to such lands as are known to have mineral or a possibility of mineral with no outcrop and then let the claim be 1500 by 1500.

If one looks into the present mining laws, there is nothing much to condemn, excepting that there should be some regulation regarding assessment work, and the mineral lands should be classified; that is, gold and silver. A claim under the present law should cover all that a prospector could ask for. If he cannot do an honest $100 worth of work per year upon such claims, he should forfeit them.

On copper and baser metals, when a prospector holds from 6 to 12 or more claims as a group, I think $25 per year of honest work performed should be sufficient. The mining law is plain and concise, but it has never been upheld or enforced. A man must make a valid discovery, he must have mineral in place, he must tie his claim to permanent monuments and objects, he must stake his property. Now what more can you ask? But the law is not carried out, and why not? Why has the Government been so slow in asserting its right to the mineral upon all grant lands? Why has it allowed timber claims to be located on mining claims and mineral lands, thus giving the miners' territory away? The reservation of the Government's mineral right upon grant lands has never held. I know that the old canal grant in the Lake Superior country had about the same recognition that the railroad grants have had. An individual buying land always found that exception in the deed, but mining corporations somehow obtained the land and mineral. Is it this that has caused the Government to be so slow about asserting its right to the mineral on railroad grants, from the fact that there was hundreds of millions at stake in the Lake Superior country?

One can forget the old canal grant, but it is time for the mining public to get together and not only recover the mineral upon all subsequent land entries, but to demand that which is theirs, that is, the mineral on grant lands and timber lands. Then frame laws that will not have a tendency to land monopoly. The law says honest discoveries must be made, but you cannot enforce these laws to the letter when the Government has been a half century trying to find out if they have the mineral on grant lands, which they explicitly specified they did have; yet officials seem afraid to reclaim that which belongs to the public.

Do not reserve anything more from the poor homesteader unless you take that which belongs to us from the grant lands. The farmer and miner have both been imposed upon. They are willing to meet on an equal footing. There has never been any trouble between them, and you will find if the miners will get together and demand the mineral belonging to them the old homesteader and farmer will be right at our backs making as much noise as any old prospector, miner, engineer, or mining professor.

I oppose an annual tax of $10 per claim; after a man patents he might be able to pay tax, but while he holds his claim under location, I believe in annual work—$100 per claim on precious metals and $25 per claim upon semi-precious metals. Let this be done upon the property. When patent is granted, it should be at $2.50 per acre and carry annual work of $25 per claim on precious-metal claims and $12.50 per claim on semi-precious claims; or privilege to pay the amount to state or Government. On failure to pay or work for a period of three years, let the land go back to the state, to work, sell, or open for relocation. Each state should be divided into mining districts and each district have a recorder of all transactions in mining. Only claims on record should be valid.

C. J. FRY.

Hutton, California, January 19.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CARBIDE LAMPS are rapidly displaeing other types in Lake Superior iron mines.

THE MASS of the sun is 332,800 times the mass of the earth, the respective diameters being 865,000 and 7918 miles. A body weighing 100 lb. on the earth's surface, would be about 3000 lb. on the sun.

AN ALLOY composed of from 85 to 87% of aluminum, 9 to 11% of zinc, 2 to 4% of lead, and 1 to 3% of a strengthening element has been patented by Charles P. Van Gundy, of Catonsville, Maryland.

TO FEED an average of 800 natives at the Lonely Reef mine in Rhodesia, in 1913, with bread, beans, mealies (corn), monkey nuts, rice, green vegetables, rations, salt, meat, sugar, cocoa, kaffir corn, milk, and maizena, cost a total of $36,500, equal to about $46 per head per year.

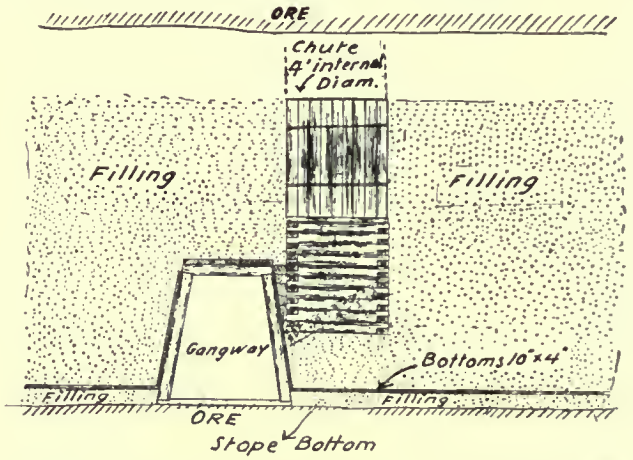
ELECTRIC POWER generated by mine power-plants of the St. John del Rey Mining Co., Brazil, during the past financial year, averaged 3314 hp. per day, at a cost of 3.2c. per 24 hours. The total output was 26,429,006 hp. hours. The mine used 60% of the power, and the mills and machine shops 36.81 per cent.

A PROCESS for the separation of bismuth and copper, which consists in reducing the bismuth copper product, consisting chiefly of bismuth and copper, to a fine state, intimately mixing therewith a suitable compound containing combined sulphur, smelting said mixture to provide crude bismuth and copper matte, and separating the copper matte from the said crude bismuth, has been patented by William Thum, of Hammond, Indiana.

TUBING for boilers consists of three classes, lap-weld charcoal iron, lap-weld steel, and seamless steel. For tubes to withstand corrosive action, lap-weld steel tubes are satisfactory, they being manufactured by a process known as roll-knobbling whereby the steel receives a kneading action, making it uniformly dense, in being worked down from the bloom to the plate. By this process it is more resistant to corrosion. The well known 'National' tube is made this way.

DUST-FALL in the neighborhood of cement plants has become a matter of considerable importance of late, as a result of litigation between certain cement companies and owners of land in the vicinity. According to J. P. Mitchell, of Stanford University, tests made at distances of from 1.2 to 2.8 miles from a plant showed the amount of cement dust falling varied from 0.4 to 10.4 lb. per acre per day, and field dust from 0.3 to 0.9 lb. per day.

'PICKING-UP BOTTOMS' is a phrase used in mining to describe the operation of removal of the last slice of ore in a stope, that is, the ore lying immediately under a level and forming the back of the overhand stope. The



SECTION OF MINE SHOWING METHOD OF PICKING-UP BOTTOMS.

figure herewith illustrates a method of mining this ore adopted at Broken Hill and described by Andrew Fairweather. Since the slice supports the bottoms of the level above, its removal necessitates picking them up; hence the phrase and its use in this connection.

MANY MINE OFFICIALS, foremen, or bosses who have spent years at a single mine do not see readily the necessity for mine signboards; because they are entirely familiar with the mine workings, it does not occur to them that the average miner cannot in a short time acquire the same familiarity with conditions. In the United States today, both metal and coal miners are largely of a roving disposition. Many of them are foreigners who are more or less ignorant of English. As a class, they require guidance in the matter of protecting themselves from accidental injury. Mine signboards are in use in many mining districts of the United States, according to Edwin Higgins and Edward Steidle of the Bureau of Mines. Although in no part of the country has the practice become general, there are isolated mines that have worked out an elaborate system of signboards. There has been no concerted action looking to the adoption of certain universal symbols or signs, although there are manufacturers of signs, and some local mining organizations now working toward this end.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

PRESENT CONDITION OF THE MINING INDUSTRY, AND FACTORS CONTRIBUTING TO IMPORTANT DEVELOPMENT.—MT. CHAMPION, DINERO, AND VIRGINIUS MINES.—ZINC SMELTER.—THE DOWNTOWN AREA.

Mining development in the Leadville district this summer shows a marked increase over that of the past several years. Three new factors have helped to this end, which combine to form the beginning of another of the great revivals that have occurred periodically in the mineral activities of this area, namely: (1) two outlying districts, which for a number of years have been considered as barren ground, are now producing a large tonnage of high-grade gold and silver ores; (2) a plant for the manufacture of zinc oxide from the lower grade carbonate ore is being constructed by the Western Zinc Mining & Reduction Co.; and (3) a leasing consolidation for unwatering the flooded area known as the 'downtown mining district' is rapidly nearing completion, and a similar enterprise is being promoted for pumping the water from the old famous Fryer Hill territory.

In the Lackawanna area and the upper Half-Moon gulch, several new mines have been opened within the past year. The Mt. Champion property is now one of the largest gold-producing mines in the Leadville district. It is situated about 15 miles from the nearest railroad, in a locality that has long been looked upon as most unpromising. Obstructions of every kind confronted the men who knew they had a mine, and were determined to develop it. A good road, eight miles long, had to be built, and machinery had to be transported to the ground, and buildings erected in a district that is noted for its severe winters and short summers. After the mine had been opened, and shipping had been under way for a few weeks, it was found that the character of the ore demanded mill treatment in order to obtain the best results. A 50-ton mill was then erected at the foot of the range, about five miles from the mine, and a tram constructed to carry the ore. It seemed impossible that a mine could be made a success under such conditions, but it is now working steadily with a force of 75 men, and producing regularly 50 tons of ore per day which averages between 30 and 50 oz. gold. The mine is now developed by three adits, all on the vein at various depths, and the manager stated recently that there was $100,000 worth of ore blocked out. Other properties are showing equally favorable results, and it will be only a question of time until there will be several large producers in this district.

The Sugar Loaf territory is the other 'no good' ground which has come prominently to the front within the last several months. Three important tunnel companies are now operating in this district, and each of them is shipping a good tonnage of silver ore. The Dinero is the most productive at present, 100 tons per day being shipped, all of which contains rich silver-lead content. The Siwatch tunnel has opened a large body of lower grade material which is being produced as fast as possible. The Virginius Consolidated properties recently developed the most important orebody that has been found for some time. A large vein of silver-bearing ore which assays up to thousands of ounces per ton was opened last month, and a steady tonnage is now being shipped. Other smaller properties are being developed, and it appears that a number of them will soon be in the producing list. The interest of mining men all through the state is centred on this and the Lackawanna country, and men who know the district say that the recent discoveries in these localities will cause a revival of mining in Leadville that will rival the palmy days of the early eighties.

The construction of the zinc-oxide plant is probably attracting more widespread attention than any other work in the district. This smelter, when finished, will handle carbonate of zinc which contains as low as 14% zinc. It will give a much more satisfactory market for the ore, and allow a more favorable contract to miners of the camp. The plant will be erected in units of 50-ton capacity each, and the first is about completed. As soon as it is in good running order, and the management is satisfied as to its efficiency, the other units will be erected as rapidly as possible, until a complete plant of 200-ton capacity is reached. The last two units will be equipped with roasting furnaces to deal with sulphide ores, and there is little doubt that if the industry proves as profitable as it is expected to be, other concerns will enter the field with similar schemes. All this tends to throw a bright light on the zinc mining of the future. Leadville is fortunate in its deposits of zinc ores, both in the carbonate and the sulphide zones. At present, several of the properties that have been idle for a score of years are being put into shape to resume operations in their zinc stopes, and as the demand grows the mining industry will keep pace with it.

The third and perhaps the greatest factor in the advance of mining in the Leadville district is the proposal to dewater the mines of the down-town district. This territory covers an area one mile square, within which boundaries some of the largest mines of the district have been found. All of the properties have been worked out down to water-level, but heretofore no effort has been made to get at the orebodies that are known to exist below this point. Jesse F. McDonald, ex-governor, together with a number of Eastern capitalists, has secured a lease on all the ground within the basin, and is now preparing to start the actual work of unwatering and developing the formations at a depth of 1000 ft. Machinery is now being manufactured for the work, and all of the operations will be done along the most modern lines. This enterprise will do more to advance the general prosperity of the district than any other now under way. It will cause the reopening of numerous idle properties, and will give employment to probably 1000 men. The success of this undertaking will induce the final agreement for the unwatering of the Fryer Hill territory, if it is not done before, and the two together will make a new Leadville.

MANILA, PHILIPPINE ISLANDS

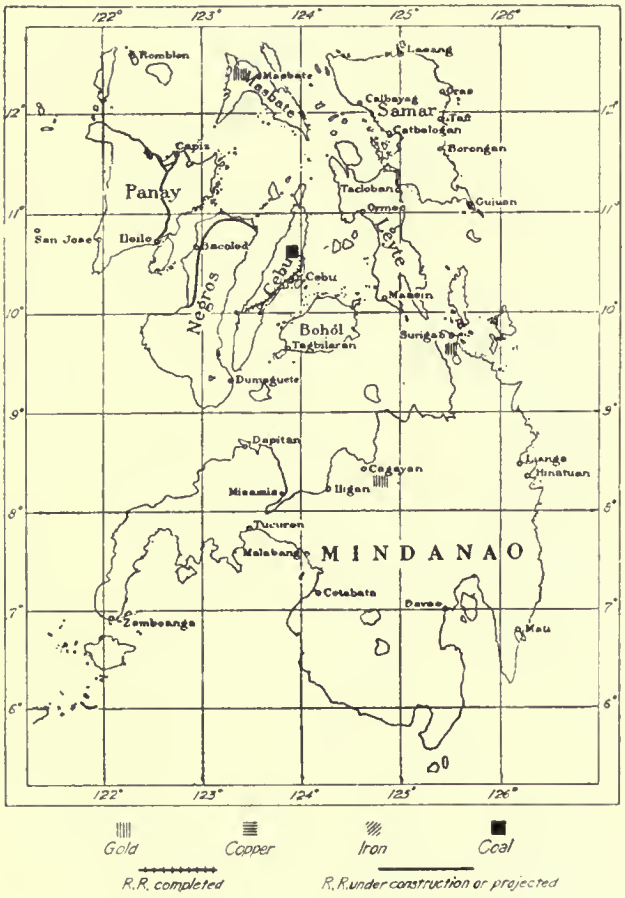
DREDGES AT WORK, AND OTHERS PROBABLE.—COLORADO, KEYSTONE, AND SYNDICATE MILLS.—IRON MINING.—PROPOSED TAX ON MINE OUTPUT.—BUREAU OF SCIENCE WORK.

Regardless of whatever else may be said regarding business in the Philippine Islands, the mining industry continues its steady development. With the starting of the new Umiral dredge, and of the new dredge on the Malaguit river, Paracale, there are now six dredges at work in the territory. Some attention has been attracted lately to the Bued river, where that river debouches into the central plain. Here prospecting has been conducted with encouraging results. One California mining man recently said that if the prop-

erty were in the Sacramento valley there would be no difficulty in securing capital to put several dredges on it at once.

An Australian, Mr. Murray, who has a patent device for saving black sands which collect on dredges, is visiting these districts. In several places black sands have been found to carry good gold content. August Heise, well known in Philippine mining fields, has returned from the United States with engineers to examine his placer properties on the Hibong branch of the Agusan river, northeastern Mindanao. Mr. Humphries, the engineer in charge, brought a steam drill with him.

Most encouraging reports come from the new Syndicate mill on the island of Masbate, as well as from the Keystone and the Colorado. The output of the Colorado is said to



SOUTHERN PART OF THE PHILIPPINES.

be a large increase over previous years. The Syndicate mill is now being enlarged.

Gold mining is still the most promising phase of the industry, but in the Angat iron-ore district conditions are favorable for a much greater production of iron and the establishment of that industry on a sound basis. On Calambayanga island, at the mouth of Mambulao bay, Mr. Cavender is erecting a cupola to smelt the iron deposits found on that island. This deposit is one of the most favorably situated of all those found in the Philippines.

Mining men have been deeply concerned lately with the attempt of the collector of internal revenue to place a tax of 3% on the gross output of the mines. Many conversant with the condition of the industry have felt that this is unjust, and would seriously cripple the industry at this time. The proposed tax was rejected by the commission. Failing in this, the collector has tried to class gold bullion as merchandise and thus bring it under a tax of 1.5%. A meeting of protest was recently held, and plans are under way to form a permanent mining association in the Philippines. It is fortunate in one way that this incident happened, as it has revealed the necessity for coöperation on the part of the mining men.

The Division of Mines, Bureau of Science, has recently lost the services of F. T. Eddingfield, mining engineer, who, after five years' service, now returns to the United States. The mining industry has profited considerably by his service in the islands, and appreciates the work he has done. Paul R. Fanning, metallurgist for three years in the division, is another good man whom the Bureau lost when the economy wave of the Democratic administration struck the islands. The two most important pieces of field work carried on by members of the Division of Mines lately are one by Warren D. Smith, chief of the division, who spent two months in north central Luzon making reconnaissances in hitherto geologically unexplored territory; and one by Wallace E. Pratt, who spent a long time on the Caramuan peninsula making silimar reconnaissances. During Mr. Smith's work, considerable mineralization was noticed in the region just east of the Cordillera Central. Whether these lodes will prove to be profitable remains to be seen.

Development work on the gilsonite deposits of Leyte has been actively started by the Bryan Landon company of Cebu and Iloilo. Fred Burdette, manager for the Camiguin North Mining Co., has begun operating on his sulphur property on the southern end of the island of Camiguin, north of Luzon. Some fine specimens of sulphur were recently exhibited by him at the Second Philippine Exposition in Manila. Mr. Seymour, a Wyoming coal operator at present in Manila, is looking into the coal situation.

KALGOORLIE, WESTERN AUSTRALIA

LABOR TROUBLES AGAIN.—GEOLOGY AND THE NEED FOR MORE INVESTIGATIONS.—EDNA MAY.—GOLDEN HORSE-SHOE AFFAIRS.

The labor unrest, which appears to be general in Australia, was in evidence in this state at the end of April. A dispute at the Edna May mine, as to whether the ground being worked was wet or dry, was settled by the manager, who agreed to wet wages; that is, above the usual rate for dry ground. Then the shovelers on the Trans-Australian railway went on strike for $3.20 per shift, the wage being paid by the contractors at the head of the line; but, though the Commonwealth Government offered an increase of 20c., from $2.80 to $3 per shift, the men are still out. The latest phase of the unrest is represented by the fact that the committee of the Federated Miners' Union unanimously passed a resolution that on and after May 1 no unionist was to work where non-unionists were employed. This step was taken in sympathy with the employees of Millars Karri and Jarrah Co., who are out on strike because four non-unionist carpenters are employed. The members of the Employers' Union promptly retaliated by passing a resolution that they would employ the best men offering, regardless of their politics or creeds, and, if any of the various unions withdrew their men on May 1, all employers of the state, in whatever industry engaged, would simultaneously close down and lock out all employees. The result of this prompt action was that the Federated Miners' Union held a general meeting on April 26, and decided to leave the question to be settled by the Australian Labor Federation at its meeting in Melbourne on May 11. It has just come to light that in two cases in which workers ceased work and broke the Arbitration Court's award, and were fined $48 and $480, respectively, by the magistrates, no fines had been paid. On this leaking out early in May, the Western Australian Government first stated that the fines had been paid, but finally admitted that they had not. Eventually the first sum was collected, but the larger one was reduced to $24 by the executive. So much for labor governments.

Ever since Malcolm Maclaren's visit to these fields in 1910, the Chamber of Mines has been urging on the state govern-

ment the advisability of increasing the geological staff, with the view to making an exhaustive examination of the gold-bearing areas to aid prospectors. To meet this demand, the government appointed five extra field geologists in 1911: but instead of attacking new ground, most of their investigations have been confined to old workings, or merely following prospectors to new finds, and drawing deductions from the few 'pot-holes' sunk. The Chamber of Mines now says that "what it wants is a systematic geological survey, as careful, as thorough, as exhaustive, and as good as money can buy, and the best qualified, the best equipped, and the most widely informed expert obtainable to draw the deductions from the data obtained." Most of the best known geologists of the world have at one time or other inspected our mines, but only one of these visitors, Malcolm Maclaren, has published the conclusions he drew from the data obtainable. Against this we have had the experience of H. P. Woodward and S. Goeczel, who joined the government mines department in 1887 and 1890, respectively, and had mapped out the gold and mineral areas of Western Australia by 1893. In his 'Handbook of the Gold and Mineral Fields of Western Australia,' published in 1894, Mr. Woodward wrote of the Great Fingall lode: "This mine is called the Day Dawn, after the first claim taken up on it. The stone is of a bluish mottled appearance, and the 'reef' is of great size and well formed. It is a true fissure vein, but does not follow any definite course, striking west-northwest, then north-northwest, and so on to the north; but this is not of the least consequence, as from its well defined walls there is very little chance of its cutting out." This mine was turned down in 1897 by the Day Dawn Co. of Adelaide, after producing £75,900 from 30,000 tons from a lens above 150 ft. It was then taken up by the Consolidated Murchison of London, and in 1898 passed on to the Great Fingall company as a derelict. A second lens was found at 460 ft. and cut out at 1370 ft., and a third at 1700 ft. which still continues. Mr. Woodward, in his 'Handbook,' pointed out in 1894 regarding the Golden Mile: "There is a large break in the country consisting principally of coarse-grained diorite extending over six miles from north-northeast to south-southwest, near the township of Kalgoorlie. Diabase (dolerite) dikes seem to have played an important rôle in the gold deposits here, and it is most probable that the gold emanation in the rich and extensive Kalgoorlie district took place in the period following these diabase eruptions." The Kalgoorlie district is the only one mentioned by Mr. Woodward and Mr. Goeczel as containing this quartz-diabase, or dolerite, and none of the other geologists who have visited the country has ever mentioned the presence of a similar area elsewhere in the state, and until that is found a second Kalgoorlie is unlikely to eventuate.

Since starting milling a year ago, the Edna May mine at Weston's, over 100 miles west of Kalgoorlie, has produced $364,000 from 16,766 tons of ore and paid $103,000 in dividends. As the residue contains $5 per ton of recoverable metal, the output and profit will shortly be materially increased when the sand and slime plants start operation. The present trouble is the fact that successive intrusions of granite eventually cut off the lode in the adjoining Greenfinch mine on the west, and similar intrusions are being encountered in the Edna May. The first bar appeared in the shaft at 124 ft., and the second has now been encountered at 200 ft. The first was only 18 in. thick, but the second is proving considerably thicker. The lode is erratic in strike, underlie, and thickness, but is wonderfully consistent in gold content, and is from 5 to 15 ft. wide in a generally east and west direction. Several adjoining claims on the east are looking promising, but the granite is making speculators shy of investing in them. No government geologist has visited the district, but other geologists wisely shake their heads and say nothing after inspecting the Edna May and Greenfinch.

In spite of the excellent developments recorded at the 2630 and 2780-ft. levels of the Golden Horse-Shoe mine, the Company continues to get deeper into debt. On January 1, 1913, the credit balance brought forward was $160,000. Since then, to the end of March 1914 the net profit earned was $105,000, a total of $265,000. Debenture interest has absorbed $25,000, debenture redemption $56,000, and dividend paid in October $288,000, a total of $369,000. This leaves a debit balance of $104,000. The position is unfortunate, and the London managing director, E. Protheroe Jones, is on his way to this country to investigate matters at the mine.

March gold returns from all mines in the state totaled $1,967,000, and dividends $578,200.

SALT LAKE CITY, UTAH

CHLORINATION APPLIED TO COMPLEX SULPHIDE ORES.—UNIVERSITY OF UTAH SOLVES METALLURGICAL DIFFICULTY.—CHRISTENSEN PROCESS.—HOLT-DERN FURNACES.

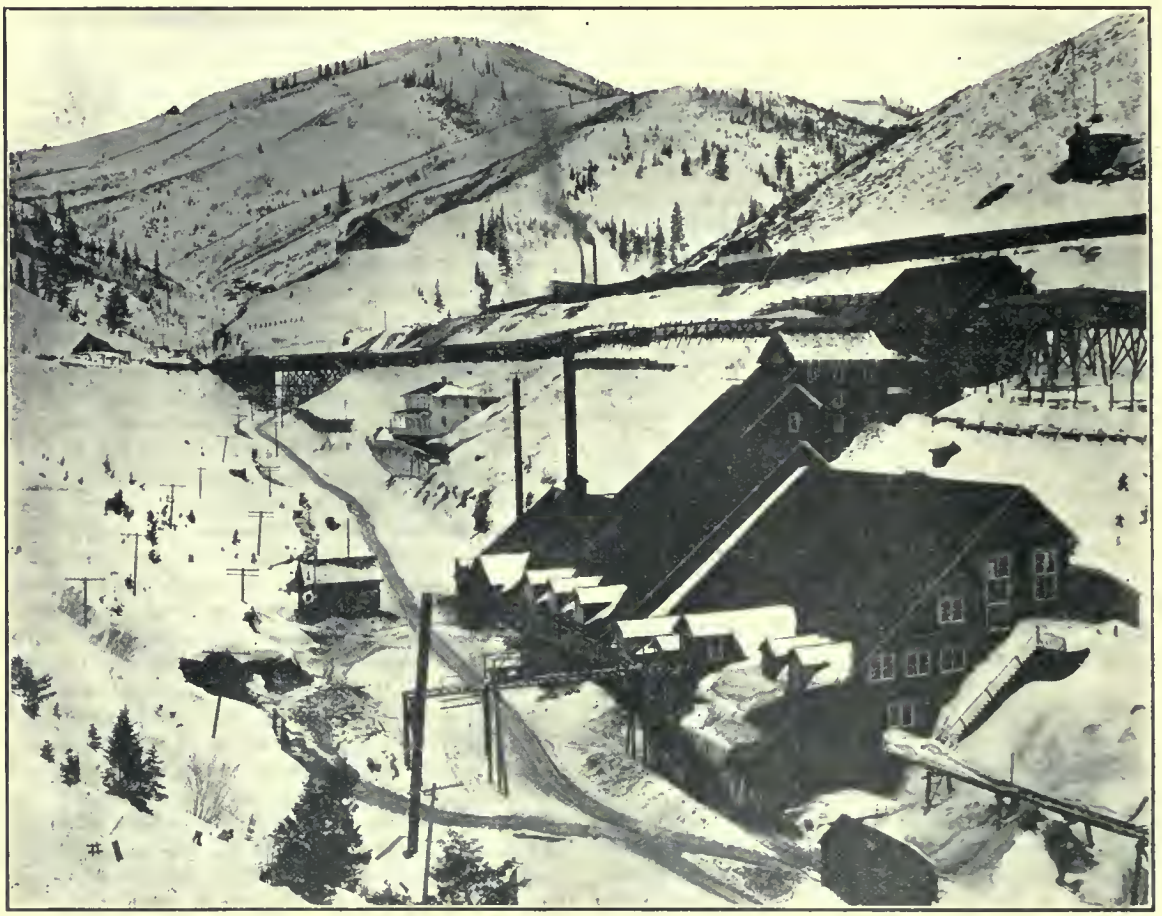
In the treatment of low-grade ore deposits Utah has long been in the lead, being the pioneer in the development of the porphyry deposits. At present it is solving the question of treating the low-grade ore containing a combination of lead, silver, copper, zinc, and gold. By July 15 there will be three mills in the state treating these ores by means of chlorination. The process is by no means new, but the methods employed are. They were worked out in the University of Utah experimental plant something over two years ago by N. C. Christensen, a post-graduate student, and T. N. Holt of the University staff. The first practical use made of the work was at the Mines Operating Co. plant at Park City, where George H. Dern and associates have a 10-year lease on the old stope fillings above the 900-ft. level of the Ontario mine. Here a great deal of experimental work has been carried out, especially in the mechanical end of the work. At present the Mines Operating Co. plant is running successfully on ore that will assay about 12 oz. silver, 2 to 4% lead, and 0.5 to 1% copper. A saving of 80% is being made. Recently a plant was built for refining the gold and silver on the ground. The second plant is at Silver City, where Jesse Knight is backing N. C. Christensen in a plant that is using the same method of treatment. The operators are just getting this mill over mechanical difficulties which caused it to run intermittently. The third plant is that of the Park City Milling Co., which, under the management of George H. Scibird, is remodeling the old Grasselli mill at Park City for the purpose of handling ores from the American Flag and custom ores. This plant it is expected will be in operation by July 15.

The method is a simple one. The ores are given a chloridizing roast by means of a mixture of salt and coal. The fumes from this roast are drawn into a condensing tower and later used for leaching the roasted ores. The chief trouble thus far encountered has been with the roasting furnace. As there was no one on the market that was satisfactory, it was necessary to devise a roaster for the occasion. At the Mines Operating Co. plant, hand-fed furnaces have been used which have been unsatisfactory in result and in economy of fuel. At the Knight-Christensen mill a round furnace with a flat revolving grate, heated by means of oil jets and a downward draft, is being tried. The roaster for the Park City Milling Co. mill has not been selected.

A new roaster known as the Holt-Dern furnace has been used for the past three months successfully at the Mines Operating Co. plant. This experimental furnace has 10 tons capacity, but has demonstrated that it eliminated dust or any volatilization of minerals. Besides that, it is declared it will save 50c. per ton in fuel. A new furnace along this line is being designed, and it is probable that all the furnaces at the Mines Operating Co. plant will, in the future, be

Holt-Dern machines, although it is declared that Dwight-Lloyd sintering machines can be used. The Holt-Dern machine it is declared roasts more evenly than any other, and actual tests have shown that a 10% greater extraction can be made from the ore. The furnace that is being designed will have a capacity of about 40 tons of ore per day. It is 8 by 10 ft., and has a depth of approximately 5 ft. The chief feature is the grates. The grates are about a foot wide each and extend the width of the furnace. Each grate is made up of iron strips or bars half an inch wide and set half an inch apart. The upper edge of the bars are equipped with half-inch teeth. Each grate is fixed to move over a roller bearing. The base for the bearing is also slotted so that the material drops down. Attached to each grate is an eccentric which has a movement or drag of 1¾ in. The eccentrics are run by the same shaft. When these are set in motion the roasted cake is practically filed off, falls down through the grates and into the hopper below. The grates are set a half-inch apart and adjacent grates have an alternate motion. Suspended through the centre of the length of the hopper below is the air-pipe which supplies the blast for the furnace. The feed is from the top, and the roast is made at the rate of about one foot per hour. Arrangements are also made for the automatic feeding of the furnace. At the top of the furnace, which has a movable cover, there is a flue through which the fumes are drawn off. This is operated by an exhaust fan.

The furnace is started by covering the grates with several inches of ore over which is spread chips soaked in oil. As soon as this is well under way, the feed, which is ore mixed with salt and coal, is started. This makes a continuous operation, with about four feet of ore and roasted material resting on the grates. As roasted ore is needed the shaking of the grates is set in motion and the ore drawn off from the hopper. Everything has been so arranged that the furnace is as nearly automatic as possible. One man can care for the feeding, the shaking, and the taking off of the roasted ore. The ore from the roaster is placed in open tanks at the Park City plant, while at Silver City it is removed to barrel tanks. The barrel tanks have a filter at one end through which the chlorine solutions are washed out. The barrel is then tipped the other way and the waste is placed on a conveyor belt and sent to the dump. The solutions pass through launders to precipitating tanks. The leaching by the barrel tanks takes about five hours.



DALY-JUDGE PROPERTY, PARK CITY, UTAH. ENTRANCE TO MAIN TUNNEL ON LEFT.

SYDNEY, NOVA SCOTIA

GOLD MINING IN GUYSBOROUGH COUNTY.—WATER POWER AVAILABLE.—NEW RAILWAY.

Within the last few months, gold mining in this province has received a little more impetus from the steady yet quiet success of one or two operating companies situated mainly in Guysborough county. During the last year a total of 7324 tons of ore was mined and crushed, yielding on the average $6.14 per ton treated. This is about the same return as the previous year. Most of the gold extracted was obtained from four mines, and of these, three, the Beaver Dam, Caribou, and Gold River, had a profitable year, the yield being $12, $14.50, and $15 per ton, respectively. In comparison with these results, the remainder of the mines in operation show a low average return. Nineteen companies in all were at work throughout the year or during part of it.

A scarcity of fuel and the transport difficulties have always been drawbacks to gold mining northeast of Halifax.

In the general advance of systematic management, attention has been drawn to the water-power of the province; and although most of the catchment areas are limited, on account of the topography of the country, still an attempt is being made to use it to advantage, to overcome in some measure the growing scarcity of wood fuel and the high cost of coal. At the mine of the Goldenville Mining Co., a dam has been built at the Liscomb falls, which gives a head of 40 ft., and this together with one of about 15 ft. provides approximately 500 hp., used mainly in pumping and crushing operations.

The building of a branch railway to pass through the mining districts of Halifax and Guysborough, running from Dartmouth on Halifax harbor northeast, and passing the heads of all the harbors on the coast of Canso and Guysborough, on the Straits of Canso, has been started. When finished, this line will be a great boon to the mining companies in regard to the easy transport of machinery and supplies.

None of the recent discoveries of tin, tungsten, manganese, and antimony ores have proved to be of any great value. On the tungsten area, only about 10 tons of scheelite was extracted, although considerable development and prospecting work was undertaken by the company. Operations have ceased entirely on the antimony areas at West Gore. The discovery of manganese, recently reported in Guysborough country, is still unproved. The ore is a fine-grained pyrolusite.

DAWSON, YUKON TERRITORY

SILVER-LEAD ORE OF THE DISTRICT, AND WORK ON THE SILVER KING, ADAM, WEB FOOT, AND MABLE CLAIMS.

Sixty-five tons of silver-lead ore, assaying $250 per ton has been hauled from the Silver King claim to Mayo landing on the Stewart river, for shipment to the Consolidated Mining & Smelting Co.'s smelter at Trail, B. C. The Silver King is situated 28 miles northeast of Mayo landing. The vein where opened is 4 ft. wide, striking approximately south 15 west with a dip of 62 east. Both walls are well defined. The hanging wall is schist, and the foot-wall quartzite. Development work is being done through an incline shaft, which has reached a depth of 70 ft. The owner of the property, H. W. McWhorter, intends to continue the shaft to the 300-ft. level this summer. On the Adam claim, 2300 ft. from the shaft on the Silver King, Mark Evans has uncovered a vein 5 ft. wide, with two bands of galena in it, varying from 1½ to 3 in. wide, which assay high in silver. As he is prospecting nearly in line with the strike of the Silver King vein, it is no doubt a continuation of the same. Owing to there being from 10 to 20 ft. of frozen gravel (glacial drift) to sink through before reaching solid formation, and which makes prospecting for the vein both slow and expensive, Jack Alvinson and J. E. Ferrel, owners of the Web Foot claim, adjoining the Silver King on the northeast, have fitted up a churn-drill to prospect with. Grant Huffman, on the Mable claim, has a shaft down 28 ft. and intends to drive and try to cross-cut the vein. Fifty-four claims have been staked and recorded in the vicinity of these properties; not having a summer road, quite a number had provisions and supplies hauled in before the snow melted and will prospect during the summer. The Yukon Council has voted for an expenditure of $17,000 for roads in this district this summer, $5000 of which will be spent building a road to the silver-lead properties. The appropriation of $17,000, while not sufficient to build many miles of wagon road in a country like this, is evidence, however, that the Dominion Government will be willing to do more as development of the district proceeds. The opening of rich silver ore has attracted a great many prospectors, and quite a number are out in the hills around here this summer. The outlook for the future is bright for this district. A stampede is neither expected nor desired. As yet the properties are in the earliest state of development. A prosperous and steady producing mining camp will be here in the near future.

NEW YORK

CONNECTICUT ZINC CORPORATION AND CHATTANOOGA COPPER CO., TWO NEW COMPANIES.—MORE ENGLISH CAPITAL IN COLORADO.—LITIGATION.

Midsummer is always unproductive of news in New York, and the events of the week are of no great significance. The Connecticut Zinc Corporation of Wyandaugh has been incorporated, with a capital of $1,000,000, to mine zinc ores in New York and Missouri. The incorporators are William G. Phillips, who has promoted other zinc mines; Michael J. Riordan, a Democratic politician of Brooklyn; and Hugh J. Moran, of Port Richmond, Staten Island. The significance of Wyandaugh is not clear; the nearest approach to the name is the village of Wyandanch, not far beyond Hicksville, on Long Island.

The Chattanooga Copper Co., capitalized at $500,000, has been organized, J. I. Carter being president; John Stagmeier, first vice-president; G. H. Miller, second vice-president; S. E. Whitaker, secretary; and P. B. Carter, treasurer. The Company owns 200 acres of land a short distance northeast of the Ducktown Sulphur, Copper & Iron Co.'s property in the Ducktown district, Tennessee, which it has been exploring by diamond-drilling. Evidently the results have been sufficiently encouraging to justify further exploration. The Ducktown district is an old one, and it would be interesting if a new producer should be developed there. Those interested in the new Company are, as the name indicates, all business men in Chattanooga.

An American property of which we hear little on this side is the St. John Mines (Colorado), Ltd., on the west side of Glacier mountain, about one and one-half miles south of Montezuma, Summit county, Colorado. Last year E. J. and E. L. A. Munby sold a group of 19 claims containing silver-lead and zinc ores to English investors, who have formed this Company. E. H. Platt has estimated that the ore reserves amount to 93,000 tons of probable ore, and 23,000 tons of stope-filling which can be milled. The milling ore is said to contain a gross content of $30 of silver-lead and zinc, while the high-grade ore now being shipped to smelters is said to yield $35 per ton net. Development work is reported as showing good ore. The mill is being remodeled. The Company is capitalized at £75,000, and 255,000 out of the 300,000 shares have been issued. For the property, £3000 in cash and £30,000 in shares was paid, while £20,000 cash and £5250 in shares was paid to the promoters.

Several large companies have had a good deal of trouble with litigation lately, and the minority stockholders in the Alice Gold & Silver Mining Co. have started a suit against the Anaconda under the Sherman anti-trust law, as mentioned in this journal of June 27. Probably nothing much will come of the suit itself except to relieve the 'psychological depression' in the legal industry.——E. A. Wall has withdrawn his petition for a receiver for the Consolidated Coppermines, and the reports which are always circulating as to the plans of that Company now say that an experimental flotation plant will be built.——W. O. Allison has succeeded in his attempt to oust F. A. Heinze from the Ohio Copper Co. New rolls are being put in the Ohio mill, and its capacity after July 15 is expected to be 3000 tons per day. Just now 2000 to 2300 tons per day is being milled.——The Old Dominion litigation still drags on its weary way. Not long ago the Court of Errors and Appeals of New Jersey, the highest court in the state, issued a decision permitting the Old Dominion Copper Mining & Smelting Co. to pay a special dividend of $10 per share, amounting to $1,620,000, out of the proceeds of its action against A. S. Bingham. Godfrey Hyams, who sought to prevent this payment, is indefatigible in litigation, however, and will doubtless at once bring fresh suits.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Chisana

Recent arrivals at Dawson state that there is nothing being found at Chisana outside of last year's discoveries. Wood

MAP SHOWING SITUATION OF CHISANA DISTRICT, ALASKA.

costs $100 per cord. It is doubtful whether there will be over 60 days' sluicing for the season.

Iditarod

A new dredge is being constructed on Otter creek for Riley and Marston.

ARIZONA

Cochise County

Large crushing machinery has been delivered at the Junction shaft of the Calumet & Arizona property. It will be ready for work in a month or so, and will handle about 1400 tons of sulphide ore per day from this and the Briggs shaft. Later on the Hoatson ore will be sent to the plant also. Cutting of the large pumping station at 1800 ft. in the Junction shaft is proceeding satisfactorily. This station will probably drain the Denn area, as well as upper levels in the Junction. The company will add to the electric equipment of its plant a belt-driven General Electric generator, 2400 amperes at 24 volts and 4800 amperes at 12 volts, with direct-connected exciter.

Through Walter Douglas, the Phelps-Dodge company has bought the Tombstone mines for $500,000 from the receiver in bankruptcy, A. L. Grow. This was the only bid for the property. Heavy flow of water has hampered work at these mines in the past.

Gila County

(Special Correspondence.)—Underground work in the Inspiration mine has been hindered by shortage of air. Another compressor is now at work supplying 3000 cu. ft., making a total of 7500 cu. ft. per minute available. At the new mill the trestle should be finished in a few days. A composition roofing material is being laid on the main mill building. A good deal of riveting remains to be done on the concentrate bins. Work is in progress on the concentrator transformer and distributing station. The latest addition to the test-mill is five Metals Recovery Co.'s pneumatic flotation machines and auxillary equipment, which are to be given a thorough test to compare their efficiency with Minerals Separation process. Although the two processes depend upon the same basic principle, the means of acquiring the final result are quite different. As soon as the necessary parts are received from the East, a series of experiments are to be started with the Bradley preliminary crushers, to determine the best steel for rolls and dies. These machines, which gave good results on a dry brittle ore, were found to wear excessively in crushing the Inspiration damp ores, but with a change to one, or a combination of modern steel alloys, it is thought that much better results will be obtained. Work is proceeding on the power-plant at the smelter site. Foundations for the turbo-generator have been poured. As the new 25-ton slag-pots, recently received, are not designed for fast haulage around sharp curves, the idea of obtaining slag from Globe for the reverberatory bases has been abandoned. Instead, a blast-furnace obtained from the Old Dominion smelter is being erected on the furnace site, so that the slag can be made as required. The furnace will probably be ready within a week, and the foundations will be poured as soon as possible, as this work is already far behind.

Miami, June 28.

Santa Cruz County

In the lengthy suit of F. J. Heney for a third share in the Three R. mine, the court at Tucson awarded him $200,000 on June 29. Full details of this case have been published in *The Oasis* of Nogales.

Yavapai County

(Special Correspondence.)—Good gold-bearing veins have been opened by prospectors on Curry creek, and Granite creek.——Two feet of galena ore has been cut at 400 ft. in the Swastika mine. It is similar to the ore shipped some time ago, and which contained up to 800 oz. silver per ton.

Mayer, June 25.

CALIFORNIA

Amador County

(Special Correspondence.)—In the suit of the Kennedy Extension Mining Co. *v.* the Argonaut Mining Co. for $1,000,000 for wrongful extraction of ore and other claims, Judge Fred H. Wood gave his decision on June 29 in favor of the Argonaut company. The latter Company is entitled to retain the gold recovered from ore from the vein in dispute. The principal issue was as to the ownership of the Argonaut vein. The plaintiffs claimed that no vein apexed in the Argonaut from end-line to end-line, and that the orebodies in dispute were not on the Argonaut vein at all, but on a vein apexing in the Muldoon claim, owned by plaintiff. The defendants upheld the continuity of the Argonaut vein, showing that it could be followed from the north end-line, underneath a lava cap, southerly through the claim beyond a point where it would cover the orebodies in dispute. They were also able to show that continuous stoping had taken place from the bottom of the Argonaut mine up to the 280-ft. level, and that from there to the claimed apex underneath the lava-capped lode line the vein could be followed all the way, although not of large or high enough value to justify further stoping.

The plaintiffs attempted to offset this demonstration of the continuity of the Argonaut vein matter by an elaborate theory of faulting, claiming first an overthrust fault, the existence of which was practically conceded by experts for both sides, and in addition to that a normal faulting of several hundred feet which they claimed would destroy the vein continuity of the Argonaut. The opinion of the court is not available for examination at this time. The case was tried for the plaintiff by Messrs. Perry and Dailey, and for the defendant by Messrs. Curtis H. Lindley and William E. Colby, all of San Francisco.——A recent cable to London showed that the Plymouth Consolidated equipment was as follows: 20% of shaft guide in place, mill 65% completed, and buildings 70% completed.

Jackson, June 30.

Butte County

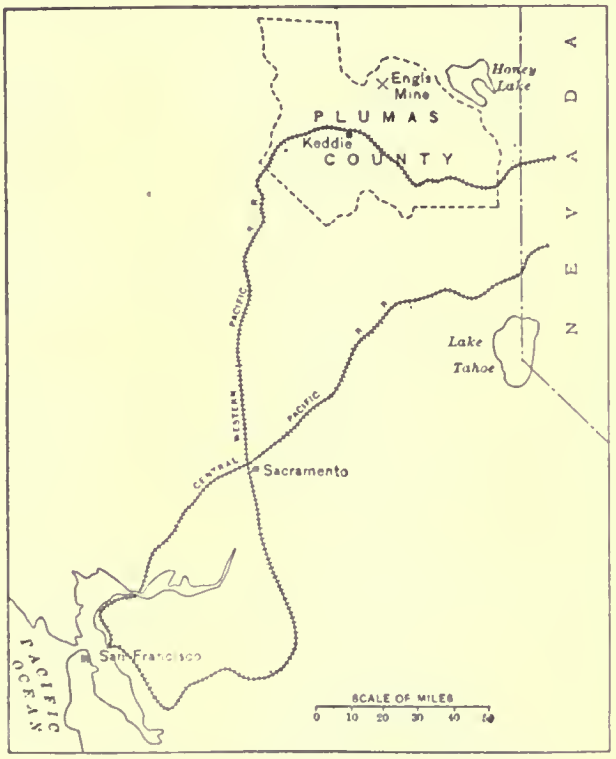
The Guggenheim interests, through their manager, O. C. Perry, have acquired a large area of ground on Butte creek, five miles from Chico. This was owned by the Drexler people. One of the Company's dredges at Oroville is to be dismantled and rebuilt on the new site this summer. The dredge operating on the American river near Auburn is returning good results.

Nevada County

The North Star Mines Co. has declared its second quarterly dividend, of $50,000, for the current year.——The Brunswick Consolidated has also declared a dividend of 6c. per share, amounting to $18,000.——The annual meeting of the Zelbright Mining Co. was held in Nevada City on June 23. Development is to be commenced on its property in Bear valley.

Plumas County

The copper deposits on the west slope of the east range of the Sierra Nevada, to the northeast of Indian valley, and



MAP SHOWING SITUATION OF THE ENGELS MINE.

embraced in the claims of the Engels Copper Mining Co., are described in *Economic Geology* for June, by H. W. Turner and A. F. Rogers. The nearest railroad point is Keddie on the Western Pacific line, 30 miles distant by wagon road. The ore in the main Engels mine occurs in a fresh massive dioritic rock. The most abundant metallic minerals are magnetite, bornite, and chalcopyrite. Pyrite is conspicuously absent. In the Superior mine, three miles away and owned by the Company, the copper minerals are chiefly along joint planes, and appear more like veins. The ore is bornite and chalcopyrite in a gangue of a green fibrous hornblende. A 150-ton mill employing the Minerals Separation flotation process is being erected to treat these ores. At present 65 men are employed under the direction of E. E. Paxton.

Sierra County

(Special Correspondence.)—A good development was made recently in the Motor gravel mine, in the Port Wine district. The gravel so far averages about $10 per cu. yd. Operations are conducted through a 1100-ft. adit. A. M. Davis is manager.——The Iowa drift mine, in the Scales Diggings district, is to be developed by San Francisco and Oakland people. An adit 2000 ft. long will be driven to cut the lava-capped channel. Wm. C. Pershbaker is consulting engineer.

Port Wine, June 25.

The Kate Hardy mine, on Oregon creek, is developing well. High-grade ore was cut recently in a raise above the main adit.

A very rich shoot of gold ore was opened in the Tightner mine at Alleghany on June 29. For several days the mine was producing about $1000 per day, and the new shoot has yielded $10,000 so far.

Tuolumne County

(Special Correspondence.)—The Omega mine has been bonded to Mrs. M. A. Capell and Mrs. A. D. Ireland, of Salt Lake City, and operations will begin immediately under the direction and supervision of Joseph Loney. The property has been extensively developed by C. W. Ayers, and is equipped with modern mining and milling machinery. It is rated among the most promising mines in the Rawhide ditsrict.——Rich ore is being extracted from a mine near Steven's bar bridge by Fred Klein, owner of the property. Good results are obtained by grinding the ore in an arrastre, but this method may be abandoned and a mill erected if prospects continue good. The vein is about 8 ft. wide.——Development work has been in progress for several months at the Louisiana mine, near Tuolumne, and within a few days the milling of ore will begin. A large compressor has just been installed.——The shaft of the App mine, at Stent, is being repaired, preparatory to active mining operations. The property is in charge of Alex. Chalmers.——The vein at the Wheal Rough, near Soulsbyville, has been cut 300 ft. below the surface, and driving east and west will be commenced at once. The vein assays well where cut.——The adit which is being driven to drain the Springfield Tunnel & Development Co.'s mine, and which will be more than a mile in length, is in 1300 ft. W. M. Hall, of San Francisco, and S. Bogle, of Tacoma, two of the directors of the Company, have just returned to their homes from a visit to the property.——The new 5-stamp mill at the Hope mine, near Sonora, has been in operation for several days, and it is reported that the ore is yielding satisfactory returns.

Sonora, June 27.

The old Sugarman mine, on Bald mountain, is yielding its owners some rich pockets of gold ore.

COLORADO

Gilpin County

After being shut down for about six months, operations are to be resumed at the du Pont-Kelley syndicate mines at Quartz hill, the German, White-Kirke and Belcher, which produce high-grade uranium ore. Forbes Rickard is manager.

Montrose County

Forty tons of carnotite ore averaging 12% uranium oxide,

and worth $43,200, was shipped from Salida to New York on June 23. It came from the Paradox field. The cost of mining and delivering a ton of this ore averages $65 per ton, of which $32 is for mining, and $25 for transport.

TELLER COUNTY (CRIPPLE CREEK)

It is expected that preliminary work on extensions of the Roosevelt drainage tunnel will be finished in a few days.—— The Howard shaft of the Mary McKinney company is to be sunk from 600 to 750 ft. Regular ore production is coming from this shaft.——Eighteen inches of ore worth $40 gold per ton, and containing seams of sylvanite, has been cut at 100 ft. in the Gold Bond mine on Gold Hill.——Rich 'float' ore has been found on some fractional claims on the south slope of Beacon hill.——The Golden Cycle company has completed a station on No. 17 level, and is now cross-cutting to the ore-shoots. The shaft is being sunk 125 ft. deeper. The electric pumps at No. 16 level are raising 450 gal. of water per minute. The Company is mining 5000 tons of ore, and 25 sets of lessees are extracting 2000 tons per month. Dividends totaling $270,000 have been paid this year.

IDAHO

IDAHO COUNTY

A good deal of interesting work is under way in the Elk City district. A 5-stamp mill is working at the Black Pine mine. H. B. Supplee is manager.——Development is being done steadily at the Colonel Sellars, and Mrs. M. A. Parr intends to erect a mill.——In the Strong claims is 8 ft. of $8 to $17 ore. A 20-ton mill is operating at the Mascot.——A. Kincaid has given a bond to Theodore L. Lammers of Spokane for the Evergreen Consolidated and Dewey groups, consisting of 14 claims, about eight miles from Grangeville, on the Clearwater river. The bond includes all equipment on the property, also a fine assay office, and water for 250 hp. from this river. About 7000 ft. of development has been done on the property in the last 15 years, and large bodies of gold-copper ore are opened. The equipment will be installed by Spokane manufacturers, and will first operate on the high-grade free-milling ores from the St. Patrick claim.

SHOSHONE COUNTY

The Yankee Boy Mining Co. shipped 271 tons of ore worth $35,461 in 1913, making a profit of $10,915. Profits of all this county's mines last year now totals $4,787,690.

The Bunker Hill & Sullivan company paid dividend No. 202, of $81,750, on July 3, making a total of $15,301,500 to date.

Men are overhauling the Blackhorse concentrator, in the Murray district of Idaho, to be used for milling the ores of the Paragon Consolidated mine, of which L. W. Stedman is manager. New rolls and a Harz jig have been installed, and it was expected that the alterations would be completed last week. The Paragon ores contain lead and zinc, and it is said the Blackhorse mill does good work separating both, saving approximately 75% of the metal content.——Work has been resumed at the St. James mine, adjoining the Sunset mine, on Sunset peak, near Wallace, owned by W. A. Clark.

MINNESOTA

One of the worst storms of recent years was raging on Lake Superior at the end of last week. Many steamers were reported in trouble and there were rumors that three sank on the north shore. All telegraph and telephone wires are down. The large steel steamer *Mataafa* stranded on the breakwater piers while trying to enter Superior harbor on June 27. She was released and towed to the Great Northern ore docks.

MISSOURI

JASPER COUNTY

The Clifford Dry Concentrating Co.'s plant at Duenweg is being dismantled, after experimenting for over a year.——A flotation plant is being operated by Hays & Thomas on the Underwriters' lease, west of Joplin. The process is a 'secret' one.

MONTANA

Montana's mine output of gold, silver, copper, lead, and zinc in 1913, according to Victor C. Heikes, of the U. S. Geological Survey, was valued at $61,900,546, against $64,754,613 in 1912, a decrease of $2,854,067, due mainly to the decreased output of gold and copper. The value of silver, lead, and zinc combined was $3,771,202 greater than in 1912, while the value of the gold and copper was $6,625,269 less than in 1912. The production of gold in 1913 was valued at $3,493,432, as against $3,625,235 in 1912. The production of silver in 1913 was 13,819,201 oz., against 12,731,638 oz. in 1912. Copper decreased from 309,738,873 lb. in 1912 to 287,828,699 lb. in 1913. Lead increased from 7,446,749 lb. in 1912 to 10,935,827 lb., in 1913. Montana's zinc ores in 1913 yielded 88,673,083 lb. of spelter, against 26,918,881 lb. in 1912.

CASCADE COUNTY

Work on the new power-plant of the Montana Power Co. at Great Falls, on the Missouri river, is so far advanced that it is likely that part of it will be in operation by January 1, 1915. At the dam, 50,000 cu. yd. of concrete has been poured, the daily rate being from 1300 to 1400 yd. Power-house foundations above water-level are finished. Six 15,000-hp. units are to be installed. About 500 men are employed in the camp. Six miles upstream, at Rainbow falls, the Company has six 6000-hp. units at work. At Thompson falls, on Clark's fork of the Columbia river, a plant of about 40,000 hp. is being constructed. The St. Paul railroad will probably take 65,000 hp. from the Great Falls plant.

SILVERBOW COUNTY

The Edith May vein has been cut at 2800 ft. in the North Butte mine, where it is 3½ ft. wide, assaying 12.5% copper and 13 oz. silver per ton.——The Anaconda company will add to the electric drive equipment of its plant 19 induction motors ranging from 25 to 50 hp., all of which have been ordered from the General Electric Company.

NEVADA

CHURCHILL COUNTY

The Nevada Hills Mining Co. reports as follows for May: Ore treated, 5300 tons; average value, $7.99 per ton; loss in residue, 80.5c.; net profit $5251; development, 548 ft.; cost, $1.08 per ton; total resources, $220,893. Profits were reduced by shaft sinking and other work.

EUREKA COUNTY

Following the addition of a toothed roll crusher, ball-mill, classifiers, a 14 by 24-ft. Oliver filter, and other apparatus, the Buckhorn mill is now treating 300 tons per day, which is almost full capacity.

ESMERALDA COUNTY

The Goldfield Consolidated Mines Co. acquired 87%, or 592,000 of 680,500 issued shares of Aurora Consolidated, which is capitalized at $1,000,000, the basis being $877,000 valuation of the entire property, including the mill which has a capacity of 500 tons per day and has just commenced operations. This price is $225,000 less than stipulated in the original option. The Knight directorate has resigned and George Wingfield was elected president. A. H. Howe, secretary-treasurer; other directors: Albert Burch, J. H. Miller, Charles E. Knox, Frank Manson, and Henry M. Hoyt. The mill was designed by Kirk and Leavell of Salt Lake City. Mr. Leavell, who remains in charge several months, will be succeeded as manager by L. H. Metzger, who has been with the Goldfield Consolidated six years, latterly as mine superintendent.

The Goldfield Consolidated Mines Co. reports as follows for May: Development totaled 2388 ft. at a cost of $6.91 per foot.

Royalty from lessees amounted to $3491, less cost of milling and transport. There was nothing of importance to report from the Combination, Clermont, and Red Top-Laguna mines The 35 sill on the new level in the Sheets-Ish section of the Mohawk mine was extended to the north, and produced 88 tons of $10 ore. On the first level in the Francis-Mohawk section, the 111-KX sill was extended and produced 112 tons of $18 ore. On the second level the 248-B sill in the Mohawk vein was extended and produced 250 tons of $10 ore. Development on the second level in the Mohawk Jumbo vein produced 188 tons of $14 ore. The 410-U sill on the fourth level in the same section produced 133 tons of $10 ore. Development in the Mohawk vein near the old 407 stope, between the third and fourth levels, produced 460 tons of $14 ore.

There was 30,181 tons of ore treated yielding a net profit of $155,049. Total costs were $5.81 per ton, including $3.07 for mining and development, $1.68 for treatment, and 5c. for examining the Aurora mine in Mineral county.

Humboldt County

Samples from the Seven Troughs Coalition mine at 1150 and 1200 ft. depth vary from $91 to $2787 per ton. On the former level 10 in. of rich ore has been opened for 190 ft. A small car of concentrate recently returned $383 per ton.

Nye County

It is reported that the large property of the Commercial Mines & Milling Co. is under option to outside capitalists. The claims included are the Crescent, Reilly Fraction, Jumping Jack, Stray Dog, Little Grey, Indian Camp, and Chipmunk, also share interests in the Mustang, April Fool, and others, with control of the War Eagle 20-stamp mill——A 50-ft. head-frame has been erected at the White Caps. The vertical shaft is to be sunk from 210 to 310 ft.——At the Associated mill, the Consolidated will use 10 stamps, a tube-mill, and cyanide plant.

During the week ended June 27 the mines at Tonopah produced 11,806 tons of ore worth $301,765.——On July 21 the Tonopah Mining Co. will declare a dividend of 25c. per share, amounting to $250,000. Profits for the last three months total $330,915.——At 1020 ft. in the new shaft of the Extension mine, the Murray vein is 23 ft. wide, averaging $20 per ton. Of this, 4 ft. of sulphide ore is worth $100 per ton.——At 980 ft. in the Merger, the ore-shoot is 10 ft. wide for a length of 200 ft.; at 1070 ft., 480 ft. long, of great width in places; and at 1170 ft., 685 ft. long, the first shoot of 400 ft. being worth $20 per ton. Shipments in 1914 to the end of May totaled 3223 tons worth $57,611.

OREGON

Baker County

The Independence mine, near Granite, has been unwatered. ——Cyaniding tailing at the Red Boy will be continued until November.——Mill machinery is being hauled from the Psyche to the Last Chance mine in Cable Cove.——There will be drilling contests between miners from the Mammoth and Columbia mines on July 4.——Work at the Buck Gulch placers has been stopped for the season.——Work is to be started at the Mayflower claims north of Sumpter.——A new company has been formed at Baker to work a limestone deposit in Pleasant valley.

WASHINGTON

Ferry County

(Special Correspondence.)—At 400 ft. in the San Poil Consolidated mine, a new orebody assaying $15 per ton has been opened. In the south end of this level a drift is being extended to cut ore developed at 300 ft. The mill is treating 95 tons of ore per day, about 30 tons coming from the Knob Hill mine. A new assay office has been built. The Knob Hill is also sending three or four cars of ore per week to smelters. More litigation has been started in this camp, as the Chicago Title & Trust Co. and W. E. Reiley of Detroit, Michigan, are suing the North Washington Power & Reduction Co. to foreclose a mortgage for $1,600,000. The case is part heard, but it looks as if the presiding judge of the court will hold that labor liens and other creditors would be considered before the mortgagee, and all creditors be compelled to share alike.

Republic, June 20.

CANADA

Alberta

(Special Correspondence.)—Dark oil is reported in the Monarch well, section 5, T. 32 N. R. 6 W. on Red Deer river. A little dark green oil was brought up in the bailer and drilling stopped until tankage could be provided. This well started near the base of the Edmonton shale and at 820 ft., where stopped, should be in the Bearpaw shales, near the top of the Montana formation.

Calgary, June 22.

British Columbia

According to J. M. Wolbert, representing Spokane, Nelson and Kaslo people, a dredge costing from $125,000 to $175,000 will be constructed on the Lardo river at Goldhill this summer. A railway runs near the site, so transport will be easy. At present, a Philadelphia syndicate is working a drag-line dredge in this district, and obtaining 75c. per cubic yard from 12 to 15 ft. depth.

Ontario

Official returns of mineral production of the province for the first quarter of 1914 show the following results: Gold ore treated, 112,826 tons yielding $10.65 per ton, of which Porcupine produced 104,880 tons averaging $10.95 per ton; silver ore treated from Cobalt (94.4% of the total), Gowganda, South Lorrain, and Casey, 163,055 tons, which yielded silver worth $190,894 less than the same period of 1913.

M'KINLEY-DARRAGH MINE, COBALT.

Trenching on the Tough-Oakes ground uncovered a new vein near No. 3. The latter averages about $120 per ton over 10 in. width for 500 ft. High-grade ore is being crushed in the mill. Metallurgical tests are being made on the ore.

Yukon

Canadian Klondyke Co.'s dredges produced 3351 oz. gold during the second week of June.

MEXICO

American employees of the Creston-Colorado, in Sonora, and El Rayo and Dolores mines, in Chihuahua, of the Mines Company of America, have returned to their respective properties for the purpose of resuming operations, or carrying on development work. No effort is being made to resume operations at La Dura, as this property is situated in the Yaqui territory, and in a district where it will be impossible for the Constitutionalists to give as good protection as in the case of the other properties.

PERSONAL

H. K. Welch has gone to Alaska.

C. C. Derby was in San Francisco.

S. J. Kidder is back from Honolulu.

A. R. Ledoux has returned from Europe.

D. W. Brunton is visiting friends in the East.

F. C. Alsdorf is in Washington examining mines.

A. G. Charleton left London for Norway on June 27.

C. W. Merrill has gone to Lake Tahoe for the month.

Charles F. Rand has returned to New York from Cuba.

Thomas T. Read is visiting the Lake Superior copper mines.

Theodore J. Hoover has returned to London from Burma.

John C. Ralston has been in New York for the last few weeks.

C. C. Broadwater was in New York last week, returning from Europe.

F. J. Basedow was in San Francisco going from Ray to Salt Lake City.

J. A. Holmes will be at Fort Bayard, New Mexico, for the next few months.

J. E. Spurr examined the Tonopah Mining Co.'s property in Nevada last week.

Marshall Draper, who has been examining mines at Nevada City was in San Francisco.

Walter H. Weed is in Butte, testifying as expert witness in the Anaconda-Pilot Butte lawsuit.

B. J. Padshah and C. P. Perin, who were in San Francisco last week, have sailed for the Orient.

C. A. Brown and J. A. Holmes, Jr. are taking motion pictures of striking mining and metallurgical scenes through the western states for the U. S. Bureau of Mines.

C. M. Means, of Pittsburgh, has been appointed consulting electric engineer with the U. S. Bureau of Mines.

Harry R. Johnson, W. R. Calvert, Ralph Arnold, and Leon J. Pepperberg are among the oil experts at Calgary, Alberta.

Edgar Rickard has been elected president of the Mining and Metallurgical Club of London. H. Livingstone Sulman is vice-president, and Sidney H. Farrar, treasurer.

W. G. Carpenter has resigned from the Goldfield Consolidated mill staff and has accepted a position with the Syndicate Mining Co., Aroroy, Masbate, Philippine Islands.

Albert Burch will have the management of the Aurora Consolidated property as well as the Goldfield Consolidated Mines Co., now that the Goldfield Consolidated has acquired control.

Arthur L. Walker has been visiting metallurgical plants in Michigan and Montana and will sail on July 9 from Vancouver for a holiday visit to Japan and China, returning by way of Suez.

Ludwig Diehl has had the title of 'professor' conferred on him by the Prussian government, in recognition of his sixteen years' work in advancing the metallurgy of gold and silver, through the use of tube-mills and other apparatus.

H. W. Hardinge left New York on June 22 for the Cobalt, Porcupine, and British Columbia districts of Canada, and Alaska. In returning he will visit most of the Western mining states. Mr. Hardinge will be gone until about the second week in August.

Karl Bernson, construction engineer for the General Electric company of Salt Lake City, has gone to Miami, Arizona, to superintend the installation of new equipment in the mills of the Inspiration Consolidated Copper Co. and the Miami Copper Co. He will later go to Superior, Arizona, to superintend the starting of the new mill of the Magma Mining company.

SOCIETY MEETINGS

JULY

SCHOOLS AND SOCIETIES

The University of North Dakota *Quarterly Journal* contains a good deal of interesting reading matter in its 70 pages.

Massachusetts Institute of Technology has published a bulletin giving names of graduates of the class of 1914, and titles of theses written by them.

The Colorado School of Mines has issued its *Quarterly*, and also a book of views of this institution at Golden. The publication deals with the college calendar, the faculty, description of the school and plant, and courses given. The summer school lasts from July 20 to August 29, and the first semester of 1914-15 starts on September 8.

Old Freibergers in America met in New York City on June 13 in honor of Dr. Friedrich Kolbeck, rector of the Freiberg Bergakademie, Saxony, Germany. Dr. Kolbeck came to this country to represent the Royal Mining School at the fiftieth anniversary of the School of Mines, of Columbia University. Dr. Kolbeck said that as he had come over to help celebrate this anniversary he hoped to see a number of former students of Freiberg back to celebrate the one hundred and fiftieth anniversary of the Bergakademie in 1916.

The Institution of Mining Engineers held its meeting in London on June 4 and 5. It was the twenty-fifth anniversary of the federation of the seven constituent institutions, namely, Manchester Geological and Mining Society, North of England Institute of Mining and Mechanical Engineers, Midland Institute of Mining, Civil and Mechanical Engineers, South Staffordshire and Warwickshire Institute of Mining Engineers, Midland Counties Institution of Engineers, North Staffordshire Institute of Mining and Mechanical Engineers, and the Mining Institute of Scotland. The total membership is 3338. The president, Sir William Garforth, who received the medal of the Institution, stated that the Duke of Northumberland was the president-elect.

Metal Prices

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

LOCAL METAL PRICES

San Francisco, July 2.

Antimony	9 — 9¾c
Electrolytic copper	15 — 15¼c
Pig Lead	4.15— 5.10
Quicksilver (flask)	$38.50
Tin	39 —40½c
Spelter	6½— 6¾c

Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 2.—As mentioned in the 'New York Metal Market Review' of this issue, repeated statements as to the depressed condition of the markets become monotonous, yet metals remain practically at the same price. Copper is firmer, with more business doing, giving better tone. June exports totaled 35,182 tons against 27,808 tons in June 1913. Granby's May yield was 1,669,334 lb. Calumet & Hecla has paid a dividend of $5, and Tennessee Copper 75c. per share. In the suit of Sidney Norman, representing minority interests of the Federal Mining & Smelting Co. v. the American Smelting & Refining Co., the New York Supreme Court gave its decision against the plaintiff. Lead and spelter are quiet. In St. Louis these metals are weaker at 3.37½ and 4.45c. respectively. Bar silver in London is steady at 26⅛d. (52.25c.).

SILVER

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

New York Metal Review

Continued reports of the depressed state of the metal trade become monotonous, but the truth permits no deviation to the side of more cheerful reports at present. One deduction that augurs well for the future, however, is the unquestionable fact that stocks of all sorts are in a depleted state, and any revival of business, especially in the metal-working trades, must be felt without delay by the producers and sellers of raw materials. The freight rate decision, now expected daily, will help in this direction; but of greater force yet is the fact that this great country is constantly wearing out enormous quantities of finished products, and these must be replaced. There is a limit to the patching which can be done. Prices may have to be kept lower than is desirable, in order to ward off too great an influx of foreign-made goods, but the United States is going to keep on making the bulk of what it uses, the production of which must support its people. June brought lower prices in copper, tin, spelter, and the products in which these materials enter. It has been a quiet month all around. Lead has been dull but steady. Tin is exceptionally low, and buying is only 'from hand to mouth.' Of antimony there is an oversufficiency in stock. Aluminum is unchanged.

COPPER

If evidence were needed as to the present dullness and low prices of the metals it might be supplied by an announcement made on June 15 by the Ansonia Brass and Copper Branch of the American Brass Co., wherein it was stated: "In view of the decline in the prices of raw materials, we beg to withdraw all prices on brass and bronze sheet, wire, rods, brazed tubing, angles, and channels, and to submit herewith a new schedule taking effect on all orders received June 15, 1914, and after." The new schedule indicated that sheet copper was reduced ¼c. to 19c. per lb. base, and that there were reductions of ⅜c. per lb. on sheet brass to 15⅛c.; brass wire to 14⅞c., and brass rods to 14⅞c. per lb. base. Copper wire in carload lots, mill shipments, was at the same time reduced to 15¼c. per lb. base. Between June 1 and 25, the copper market declined about ½c. per lb., and the dullness was without relief. The quotation for electrolytic on June 1 was 14.12½c. cash New York, while on June 25 it was 13.62½c. cash New York, with a tendency toward still lower prices. Of course, there was some business during this period, but it was mostly in small lots for prompt shipment to meet current requirements. Consumption is estimated as being between 60 and 70% of normal. In the first day or two of the month the offerings at substantial concessions outnumbered the takers, with second hands, rather than the producers, pressing for business. European buying slackened up considerably, although exports against old transactions kept up well, those for May having totaled 30,777 tons. The June exports, up to the 27th, amounted to 29,388 tons. The May report of the Copper Producers' Association, out June 8, showing that stocks had increased 14,005,640 lb., was construed as unfavorable, and the electrolytic market at once dropped ¼c. In this instance, and again later in the month, the producers did not publicly announce a reduction, but the price came down, nevertheless. Toward the end of the month the market could only be described as stagnant, buyers showing no interest, and there being no pressure to sell on the part of either producers or second-hands. Prime Lake shared the decline, though it did not come down in proportion to electrolytic. On June 1 it was quoted at 14.37½c., while 24 days later it could have been had at 14.12½c. cash New York. Inferior grades of Lake were to be had at 14c. and lower. Early in the month, prime Lake was sold at 14.25c., and other grades not regarded as prime, at a shade under 14c.

The apparent consumption of copper in the United Kingdom, as per the Board of Trade returns, in the first five months of this year, was 53,319 tons, as compared with 45,633 tons in 1913.

LEAD

Dull, but steady, sums up the lead market in June. Prices were unchanged at 3.90c. New York and 3.80c. St. Louis. Toward the end of the month the patience of sellers was becoming exhausted, and they complained of the lack of orders. Just at the end of May a good sale was reported, a New England ammunition maker taking 1000 tons on a basis of 3.95c. delivered. Early in June there were reports that inquiries from Europe had resulted in sales, but the business could not be traced. Despite the quiet, there was little or no disposition to shade prices, and the market was in all respects a waiting one.

SPELTER

While the request for spelter was quiet, there was promise of a better demand from the sheet mills, which toward the end of the month began to feel a disposition on the part of their customers to buy sheets for the third quarter. This was offset, however, by the prospect of trouble between the sheet mills and their employees over the wage scale for next year. A conference which was held at Atlantic City did not bring any agreement between them, and the situation was left with the possibility of a shut-down of about 22% of the sheet-mill capacity of the country unless further conference was successful. Until near the last of the month, quotations were unchanged at 5.10c. New York and 4.95c. St. Louis, then five points were lost, making the price 5.05c. New York and 4.90c. St. Louis. Of course, the metal was adversely affected by the slack business of the brass mills.

TIN

The market ranged between 30 and 31c. from June 1 to June 27, with buying light at all times. Nearly all of such activity as prevailed was in comparatively small lots for prompt or very early delivery, an evidence of the depleted state of consumers' stocks. Deliveries continued good, principally because of the large consumption of the tin-plate mills. In May, deliveries totaled 3800 tons. On June 2, the London price dropped £5, causing a break here of over ½c., and about 150 tons changed hands as a result. The London market at this time was in a more or less demoralized state, because of a lack of support which left it at the mercy of the bears. In New York, conditions were not pleasing either, as some of the metal taken June 1 by consumers under contract, had cost them 40c., while the quotation on that day was 31.25c., and the next day it dropped to 30.45c. It was noted that dealers lost no time in making deliveries on such contracts. Abroad, the unsatisfactory condition was attributed to the world supply statistics, the shipments from the Straits having been 788 tons larger in May than those of the same month last year. In five months of this year the Straits shipments were 1774 tons greater than those of the same months in 1913. The middle of June brought no betterment, either in the number or character of sales, and a serious development at this time was a failure to take certain deliveries against an old contract. On June 15 there was a sale, under the rule, on the floor of the New York Metal Exchange of 25 tons, ex-steamer *Atholl*, which brought 29.50c., the lowest price in years. Spot supplies were closely concentrated. As the month drew near its close, consumers seemed to have but little faith in the market, were showing no interest in futures, and all sides seemed to be awaiting developments. The arrivals in June, up to the 27th, totaled 3200 tons, and there was afloat 2308 tons. In five months of this year deliveries decreased 450 tons as compared with the same time last year. The total visible world supply June 1, was 17,862 tons, as compared with 13,710 tons June 1, 1913. On June 25, London declined between £4 and £5 and the New York price dropped to 29.87½ cents.

ANTIMONY

The demand has been poor and the supply over-sufficient. Stocks in bond, June 1, were reported at 1,361,354 lb., as against 4,445,599 lb. on the same date a year ago. These amounts cannot be compared, however, for the reason that a year ago a change in tariff was impending and all the metal was carried in bond, whereas now a great deal is stored in private warehouses. With but slight changes the following prices ruled through the month: Hallett's, 6.87½ to 7c.; Cookson's, 7.12½ to 7.20c., and other grades, 5½ to 6c. per pound.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.
6s-12 oz.-10s	8¾	6s-14 oz-20s	9½

*Extra charge for packing nitric acid for shipment to conform to regulations.

Petroleum Production of the United States

After making a complete investigation of this industry, the U. S. Geological Survey has compiled the following table. The totals are only 2.5% different from preliminary estimates published by the Survey eight days after the close of the year 1913. The Survey is the only statistical agency which prepares a statement of the value of the crude oil at the wells. The principal feature was the gain in value over 1912, namely, $72,908,141, although the output was only 25,511,186 bbl. greater. Every state except Colorado showed an increase in the value of the oil.

	1912.		1913.

COMPANY REPORTS

COLOMBIAN MINING & EXPLORATION COMPANY, LTD.

The report of this Company, operating at Marmato, Colombia, deals with the year ended March 31, 1914. In the Colombiano mill of 40 stamps, Cien Pesos of 22 stamps, and Infierno of 10 stamps (now 20), owing to a shortage of water, only 25,494 tons of ore was treated, yielding $7 per ton in gold. A plant is being erected to treat the sand, which averages $8 per ton. The value of gold recovered was $240,000, an increase of $48,000 over 1912. Ore reserves in the different mines are estimated at 136,344 tons averaging $10.50 per ton. Good progress has been made with the new mill at La Palma. It consists of rock-crushers, 40 stamps, two Dorr classifiers, three tube-mills, two Dorr thickeners, six Paterson agitators, and 10 Dehne filter-presses. Labor and transport arrangements continued satisfactory.

ROBINSON GOLD MINING COMPANY, LTD.

During January of the current year, it was proposed to amalgamate this great Rand company with the Crown Mines, Ltd., but shareholders objected to this being done. The report for the year ended December 31, 1913, contains the following information: Owing to the gradual reduction in the number of stope faces capable of supplying large quantities of the higher-grade ore, the increased tonnage was made up from development ore from surface dumps, and Main 'reef'. This resulted in a fall in yield of $1.90 per ton milled, and a decrease in working costs of 38c., with a reduction in working profit of $390,000. A small amount of development was done on the lowest levels, disclosing good ore in each reef. The development of the mine is now practically completed. Ore reserves are as follows: Leader, 349,000 tons of $10.20 ore over a stoping width of 82 in.; South reef, 189,200 tons of $11.1 ore over 65 in.; and recoverable from old workings, etc., 469,100 tons. There is also estimated to be in the Main reef, 772,900 tons of $4.30 ore. Sand-filling of stopes was done for about nine months.

Results were as follows:

	1913.	1912.
Ore mined, tons	700,149	673,058
Ore from surface dumps, tons	26,734	.....
Sorting done, per cent	8.1	13.8
Ore milled, tons	668,900	577,300
Yield per ton	$ 8.58	$ 10.18
Total yield	5,750,000	5,900,000
Working profit	3,500,000	3,940,000
Working cost per ton	3.38	3.76
Dividends paid	2,010,000	2,970,000
Transvaal Government tax on profits	312,000	.....
Balance unappropriated	$2,490,000	.....

BROKEN HILL PROPRIETARY BLOCK 10 COMPANY, LTD.

The report of this New South Wales Company covers the half-year ended March 31, 1914. Development totaled 1112 ft. At the beginning of the term the management adopted the policy of confining all development work to the upper levels, from the 615 ft. level upward. No work was done in the lower levels, except making necessary repairs, and providing an emergency escape from the 1215-ft. level into the neighboring Proprietary mine. The main drift at 615 ft. followed the ore for about 200 ft. southwest, and it looked as if it would connect with the western orebody discovered in the Central mine. But it turned almost due east, with the result that at 311 ft. the ore passed over the boundary of the Central mine at a point within a few feet of the Block 10 old main-lode workings. Ore reserves are about 228,900 tons.

The new mill did good work in treating 48,739 tons of ore, yielding 6752 tons of lead concentrate. Metal recoveries were: Lead 74.8%, and silver 47.8%. A total of 73,809 tons of concentrate, current by-products, dump tailing, slime and middling was sold, the total revenue being $410,000, and net profit $31,000. A dividend of $144,000 was paid, and the surplus reduced from $485,000 to $440,000. Costs were as follows: Mine development, 34c.; ore extraction $3.84; milling, treatment, and transport, $1.44; and general, 24c., a total of $5.86 per ton.

ST. JOHN DEL REY MINING COMPANY, LTD.

The eighty-third annual report of this Company, operating in Brazil, covers the year ended February 28, 1914. The superintendent, George Chalmers, commented as follows on the work done: The average number of native men and women employed was 2408, and of officers and English employers there were 170. Early in 1912, labor troubles started, and the climax was reached in September and October, 1913. Efforts at recruiting labor in Brazil and other countries were not successful. While the government was prosperous, and paid good wages for work being done, men kept away from the mines; but when rubber and coffee prospects were poor, it retrenched, and men returned to the mines. A rise in wages was necessary and increased the costs considerably. Among the attempts to help the labor difficulty was the importation of 107 Japanese. They arrived on August 30, 1913. They were a sturdy lot and well disciplined, and great consideration was shown them. But only 10% of them would go underground, in spite of patience of the mine staff. In October, they started to desert, and at the end of the Company's year the 107 Japanese had gone. The experiment was therefore a failure. The mine is a fairly hot one, and this is a reason for men not liking to work underground. There were five fatal accidents in the mine, mostly due to the mens' own carelessness. The general health of Morro Velho was good. The medical officer treated a total of 24,755 patients, most of whom consulted on trivial cases. Tuberculosis is on the increase here and throughout Brazil.

The Morro Velho and Raposos tramway started operation on April 5, and handled 14,937 tons of stores, ores, and 32,725 passengers. It is showing a small profit, but is generally a great convenience. Cost of transport from Honorio Bicalho used to be $3.81, but is now reduced to $1.76 per ton.

At the mine, a total of 2588 ft. of work was done. Ore reserves are estimated as 887,400 tons, compared with 813,788 tons in the previous term, and are estimated to 122 ft. vertical below last year. No. 18 level is 5226 ft. below the surface, 1902 ft. below the adit, and 2458 ft. below sea-level on the incline. Electric locomotives in the adit worked well, and it is proposed to substitute these for mules in the lower levels. The Sirocco fan is now driven by a 300-hp. motor, increasing the volume of air delivered 22%. Another fan will be installed at the top of 'G' shaft. Stope-filling for the year amounted to 135,573 tons.

The stamp-mill crushed 171,000 tons of ore yielding 97,208 oz. gold, worth £411,508. The recovery by all processes was 93.13 per cent.

Costs were as follows: State and Federal government duties and transport, 60c.; development, 41c.; working charges in Brazil, $7.30; and London expenses, 10c., a total of $8.41 per ton. The profit was £115,349. Dividends amounting to 24c. per share, or 10%, were paid. The balance carried forward is £7196. Investments are worth £96,172.

Owing to the shortage of labor, development and sampling of the extensive iron-ore deposits was suspended. Foreign capital has secured all of the other first-class iron land for a radius of many miles from the mine, and the general tendency of these owners is 'watchful waiting.'

Brazilian exchange for the Company's drafts averaged 16.088d. (32.176c.) per milreis. Mine temperatures will be discussed in another issue of this journal.

MINERAL STATISTICS

THE FOLLOWING DATA, COVERING THE YEAR 1913, IS FROM THE UNITED STATES GEOLOGICAL SURVEY:

COAL MINING IN MISSOURI

Coal production in Missouri in 1913 was 4,318,125 short tons, valued at $7,468,308, a decrease compared with 1912 of 20,731 tons in quantity and of $165,556 in value. With the exception of 1912, however, the output in 1913 was the largest in the history of the state. The number of fatal accidents was reduced to just one-half of the fatalities of the preceding year, or from 20 to 10, according to reports to the Bureau of Mines.

COAL MINING IN INDIANA

Coal production in Indiana in 1913 was 17,165,671 short tons, valued at $19,001,881, according to Edward W. Parker, Although this was an increase of 1,879,953 short tons, or 12.3% over 1912, it fell short of the record output of 1910 by more than 1,200,000 tons and was withal far from satisfactory to the producers. Floods and a drought interfered with regular work. The average value per ton showed a decline from $1.14 in 1912 to $1.11 in 1913. The total value of the coal mined increased from $17,480,546 to $19,001,881, a gain of $1,521,335, or 8.7%, compared with the increase of 12.3% in quantity.

In spite of the adverse conditions which prevailed in 1913, labor was in better supply and the number of working days made by the employees was greater than in 1912. The total number of employees in the coal mines of Indiana increased from 21,651 in 1912 to 22,235 in 1913, and the average working time from 182 to 190 days. The average annual production per man increased from 706 to 772 tons, and the average daily production by each man from 3.88 to 4.06 tons. The increased efficiency was due in part to the larger proportion of the product being mined by the use of machines, the increase in that item contributing 66% of the total increase, or 1,270,387 tons. The production of machine-mined coal in 1913 amounted to 9,634,146 short tons, or 56% of the total, compared with 54.7% in 1912. The number of fatal accidents reported to the Bureau of Mines for 1913 was 66, compared with 40 in 1912.

METAL PRODUCTION OF THE EASTERN STATES

The following table, compiled by H. D. McCaskey, shows the output from 90 mines, of which 48 were gold-placer, 9 zinc, and 7 copper properties. Of the gold mines, 27 are in Georgia, 17 in North Carolina, and 4 in South Carolina. Nearly all the copper came from the Ducktown district of eastern Tennessee. The zinc mines at Franklin Furnace, New Jersey, produced the bulk of that metal:

State.	Ores mined. *Short tons.*	Gold. *Value.*	Silver. *Fine ounces.*	Copper. *Pounds.*	Lead. *Pounds.*	Zinc. *Pounds.*	Total value.
Alabama	4,068	$ 11,094	117	.....	.....	.....	$ 11,165
Georgia	2,614	15,108	75	.....	.....	.....	15,153
New Hampshire	400	.....	.....	.....	.....	30,000	1,680
New Jersey	490,434	.....	.....	.....	.....	168,244,000	9,421,664
North Carolina	11,274	126,448	1,812	.....	.....	20,400	128,685
Pennsylvania and Vermont	239,178	3	105	517,692	.....	.....	80,309
South Carolina	1,010	4,881	40	.....	.....	.....	4,905
Tennessee	823,645	7,595	108,105	19,390,750	1,632,000	11,166,000	3,703,752
Virginia	30,916	604	960	56,287	.....	5,438,000	386,244
Total, 1913	1,603,539	$165,733	111,214	19,964,729	1,632,000	184,898,400	$13,753,557
Total, 1912	1,361,734	$222,496	96,523	19,265,945	561,026	144,699,863	$13,470,276

PUMICE

Pumice produced in the United States in 1913 amounted to 24,563 short tons, valued at $55,408, a decrease of 2583 tons in quantity and of $31,279 in value compared with 1912. The material came from six states, namely, California, Kansas, Nebraska, Idaho, South Dakota, and Utah.

OILSTONE

The production of oilstones, including hones and whetstones, and scythe-stones in the United States in 1913 amounted to $207,352, a decrease of $24,866 compared with 1912, according to Frank J. Katz of the U. S. Geological Survey. Oilstones were produced in Arkansas, Indiana, Ohio, and Kentucky, especially in Arkansas, which has led in the production for many years. New Hampshire led in the production of scythestones, but Vermont, Ohio, and Michigan also contributed important quotas.

PORTLAND CEMENT PRODUCTION

During 1913, according to final figures collected by Ernest F. Burchard, the output was 92,097,131 bbl., an increase of 11.72% compared with 1912. Shipments by states were as follows:

State.	Shipping plants.	Quantity, barrels.	Value.	Average price per barrel.
Pennsylvania	23	28,060,495	$24,268,800	$0.865
Indiana	5	10,219,492	10,218,867	1.000
California	7	6,018,262	8,896,734	1.478
New York	8	5,136,334	4,801,607	0.935
Illinois	5	4,734,540	4,784,696	1.011
Missouri	5	4,485,820	4,556,822	1.016
New Jersey	3	4,255,015	3,638,755	0.855
Michigan	11	4,081,281	4,228,879	1.036
Iowa	3	3,455,800	3,972,876	1.150
Kansas	10	3,291,818	3,286,861	0.998
Texas	4	2,108,737	2,663,063	1.263
Washington	5	2,023,172	2,853,260	1.410
Ohio	5	1,631,055	1,721,423	1.055
Utah	3	950,469	1,233,421	1.298
Other states*	16	8,237,087	7,980,911	0.969
Total	113	88,689,377	$89,106,975	$1.005

*Alabama, Arizona, Colorado, Georgia, Kentucky, Maryland, Montana, Oklahoma, Tennessee, Virginia, and West Virginia.

In 1912 there were 117 shipping plants, moving 85,012,556 bbl. valued at $69,109,800, an average of 81.3c. per barrel. In 13 states, in the above table, there was an increase in the price of the product.

Total recovery of useful fuel from waste heaps and culm banks, at coal mines in the United States, has amounted to 49,329,376 tons since 1890.

BOOK REVIEWS

METALLURGY OF COPPER. By H. O. Hofman. McGraw-Hill Book Company, New York. P. 556. Index. For sale by the *Mining and Scientific Press*, San Francisco. Price $5.

The aim in the preparation of this book as stated by the author has been to meet the demands of the copper metallurgist of today, and toward this end Mr. Hofman has succeeded in compiling a vast amount of information on the subject. The work presents the leading physical and chemical facts about copper, its alloys, and compounds which are of metallurgical importance; details of the older smelter practice which are of value together with the modern methods and recent developments in copper metallurgy with examples taken from the modern American plants are presented in detail. The work opens with a discussion of the properties of copper, its grades, impurities, and their effects. The industrial alloys are discussed with eutectic curves, and the compounds and ores of copper are briefly treated. The author devotes 340 pages to the smelting of copper in which space the numerous phases of the subject are dealt with, special attention being given to the dynamics of copper smelting. The pages are replete with detailed drawings of smelter equipment.

The leaching of low-grade and finely desseminated copper ores, which has of recent years come to be such an important branch of copper metallurgy, forms an important part of the work. A general discussion of the chemistry of the subject is followed by descriptions of the various leaching processes with apparatus for use in this branch of metallurgy. The electrolysis of ore, matte, speise, and metallic copper in general is discussed. The current, cells, and equipment for the electrolytic refining of copper form the subject of this department of the book. The bibliography presented is an important asset as the numerous references which are given as foot-notes cover the literature on the subject and are valuable as reference for one caring to go into further refinements of the subject. The work is a valuable addition to the literature on copper metallurgy and is of particular interest as a text or reference work.

CHEMICAL GERMAN. By Francis C. Phillips. The Chemical Publishing Co., Easton, Pennsylvania. P. 241. Notes, vocabulary. For sale by the *Mining and Scientific Press*, San Francisco, California. Price $2.

Practically every engineer who, by necessity or inclination, has occasion to make a careful survey of the literature on any subject finds it necessary to read papers appearing in German and French, since one or the other of those two languages is used not only by their respective nations, but also by scientific workers in almost every other European country. In the case of French, this involves little difficulty, since technical French is lucid and anyone who can read, even with some difficulty, an ordinary French novel, finds less labor required to comprehend a scientific paper. German, on the other hand, presents the reverse characteristics, and an engineer who successfully passed the examination in German for entrance to his technical school and for whom the American *rathskeller* or travel in Germany has no terrors, not infrequently gives up in despair when confronted with the necessity of reading an article written in technical German. Many of the words used in such an article are not to be found in any ordinary dictionary, or if they appear their technical meanings do not. The German method of naming compounds is also puzzling; thus *Zweifachschwefeleisen* (FeS_2) and *Zyanwasserstoffsaüre* (hydrocyanic acid) are not at once recognizable. Superimposed on these difficulties is the controversy raging in Germany between the advocates of simplified spelling and those who adhere to the old style, so that between the *volkstumliche Schriebweise* and the *wissenschaftliche Schreibweise* the student is apt to become hopelessly entangled. Mr. Phillips, who is professor of chemistry in the University of Pittsburgh, has come to the aid of the chemical student, and by giving him the rules which govern chemical German, an excellent vocabulary of chemical terms as well as ordinary words used in chemical sense, and a series of graded extracts from chemical literature, enables him to find his way through chemical literature and to equip himself to proceed unaided. A similar guide to geological and metallurgical German is greatly to be desired, but pending its appearance American students will be greatly aided by this volume, for which Mr. Phillips deserves and will doubtless receive the thanks of every plodding research student.

MINING DECISIONS

OIL LEASE—RIGHT OF ACTION

Where an oil lease by its terms leased the land therein described and not merely the right to extract oil therefrom, the lessee could maintain an action thereon prior to the discovery of oil.

Kline *v.* Guaranty Oil Co. (California), 140 Pacific, 1. March 25, 1914.

CORPORATION LIABLE FOR VIOLATION OF STATUTE

Those in charge of a mine for a corporation must see that the statute against mining within five feet of a division line is observed, otherwise the corporation is itself liable for the penalty. The neglect, mistake, or disobedience of its servants in this particular will not excuse it.

Gawthrop *v.* Fairmont Coal Co. (West Virginia), 81 Southeastern, 560. April 7, 1914.

COAL LEASE—IMPLIED COVENANTS

A lease of "all coal and mineral rights and privileges whatsoever, contained on, in and beneath the surface", of certain described land, for a period of ninety-nine years upon a consideration of royalties, but with no covenants for diligent working by the lessee, was held to be a lease upon an implied covenant for reasonable diligence on the part of the lessee, vesting no estate in the coal until actually mined. A lapse of twenty-five years before commencing operations was held to warrant a forfeiture.

Chandler *v.* French (West Virginia), 81 Southeastern, 825. May 21, 1914.

ASSIGNMENT OF OIL LEASE—HELD VALID

An oil lease was granted upon condition that a well should be commenced within a year, or in lieu thereof $160 paid to the lessor. A year elapsed without compliance by the lessee with either of these conditions. A new lease was then made by the lessor to third parties, who assigned it to the defendant for a consideration. Before all the consideration was paid, the original lessee paid $160 to the lessor. The assignee thereupon refused to pay the balance of the consideration for the assignment of the new lease, alleging that the old lease had been continued in force by the acceptance of the delayed payment and that there was a breach of implied warranty. Held, that the assignor of the new lease was entitled to recover the balance of his consideration, as the $160 had not been paid within the year and could not validate the old lease after the new one became effective.

Eastern Oil Co. *v.* Holcomb (Oklahoma), 212 Federal, 126. February 23, 1914.

New Machines and Devices

The Use of Link-Belts

The detachable link-belt was invented by William D. Ewart in 1873, and since that time the original link-belt has been manufactured at the Ewart and Belmont works of the Link-Belt Company at Indianapolis. Link-belts are adapted to such a wide variety of uses and their construction is so well understood that the engineer and millman, who has occasion to use them, thinks little as to their technology and correct application. The two qualities most desired in chain drives are, of course, immunity from break-downs and durability, both of which can be secured by using the proper belt for the working load. The magnitude of this load depends upon the speed of the chain and the character of the work which the chain is to perform.

In transmitting power the engagement of each chain link with the tooth of the sprocket wheel is attended by a certain degree of shock, and as this is multipled and intensified as the speed is increased, the working load of the chain shonld be reduced in a compensating ratio.

As the result of numerous and carefully conducted series of tests, the Link-Belt Co. recommends that the working load of the chain be determined as follows:

For a speed of 200 ft. per minute and under, divide average ultimate strength by 6.

For a speed of 300 ft. per minute and under, divide average ultimate strength by 8.

For a speed of 400 ft. per minute and under, divide average ultimate strength by 10.

For a speed of 500 ft. per minute and under, divide average ultimate strength by 12.

For a speed of 600 ft. per minute and under, divide average ultimate strength by 16.

For a speed of 700 ft. per minute and under, divide average ultimate strength by 20.

If the load to be transmitted is irregular or subject to shock, or if the chain is used in an elevator or conveyor handling gritty or coarse material, a still further reduction of the working load must be made. The ultimate strength of the chains is obtained from the manufacturers' catalogs. The horse-power transmitted may be ascertained by multiplying the number of feet the chain travels per minute by the working load and dividing the result by 33,000.

Manganese steel has been adapted for link-belts where special toughness and hardness is required. By special processes, mixtures, and heat treatments, it has become possible to manufacture smooth and uniform chain links of the various types used for severe work. The characteristics of the manganese steel used for link belts are its extreme toughness, it not being brittle, but so ductile and malleable that when overstrained it will stretch and twist out of shape instead of giving way suddenly.

In the operation of link-belts it is essential that the sprocket wheels are carefully fitted to the chain. It is true that chains will frequently 'run' on sprocket wheels which do not fit them, but to insure durability and maximum service of both chain and wheel, they must fit. A sprocket wheel with hardened face that does not fit the chain may have a long life, but at the expense of the chain. It is necessary, therefore, that when sprocket wheels are purchased it be insisted upon that they fit a chain of standard pitch. Smooth hard bearing surfaces for contact with the links and a careful fit insure the chain against undue wear.

A recent publication of the Link-Belt Co., represented on the Pacific Coast by the Ely Machinery Co. of San Francisco, entitled 'Advance Section A' of general catalog No. 110, describes in detail the numerous chain belts and sprocket wheels manufactured by this Company.

New Deister Products

The Deister Machine Co., of Fort Wayne, Indiana, during the past year has placed a number of new machines on the market, for which there is claimed marked advantages over the older products. Among these it is claimed that the simplex double-deck slime concentrator will handle twice, and the simplex double-deck sand concentrator four times, the tonnage handled by the respective older type single deck tables. The capacity of the six-deck tilting slimer is said to be four times that of the old type single-deck slimers. The Company states that the multiple-deck machines are no longer an experiment, but on the contrary have proved a great success. They have been in continual operation in one of the most up-to-date mills in the country for over a year, and are so rigidly tied together and mounted that they have given no trouble mechanically. In connection with these machines, a blueprint is furnished for a stationary pulp distributor which provides for an even distribution of feed to the decks. The Deister Machine Co.'s 'Ideal' headmotion is interchangeable and is used on all the latest sand and slime tables manufactured by this Company. Every millman knows that the headmotion is the important factor in the operation of a concentrator. Simplicity, durability, and efficiency of the 'Ideal' headmotion, it is claimed, has been demonstrated in nearly a year's constant operation. During this time, it required no attention other than the regular oiling. The principal wearing parts are made of case-hardened steel and run submerged in oil. It can be adjusted, while in operation, by an adjustable eccentric pin in the rear of the motion. This adjustment is independent of the means for adjusting the stroke. The Company also equips decks of other types of concentrating tables with the patented plateau and riffling system, and thereby proposes to increase the capacity of these tables without decreasing their efficiency.

Commercial Paragraphs

The June number of 'Leschen's Hercules,' the monthly publication of A. Leschen & Sons Rope Co., contains an interesting description of the application of flattened strand rope to coal mining operations in Utah.

The Western Electric Co., of New York City, has for distribution a most interesting publication entitled 'The Making of the Voice Highways.' The publication presents a pictorial review of the history of communication and modern wire and cable making. The subject-matter is attractively presented and of an educational nature.

An enormous conveyor belt was recently made in Australia by the Dunlop Rubber Co. for the Broken Hill Proprietary company. It is 4875 ft. long in seven sections, 36 in. wide, ¾ in. thick, 6 ply in the centre, 9 ply at the edges, weighs 30.5 tons, and is to run at 250 ft. per minute. It will be used in loading ironstone from the Company's deposits in South Australia into vessels for conveyance to Newcastle, New South Wales, where a large iron and steel plant is being erected.

THE Circuit Court of Appeals at San Francisco re-affirmed its decision in the case of Minerals Separation, Ltd., *versus* James M. Hyde, on July 6. Minerals Separation now has sixty days within which to move in the matter of getting the case before the United States Supreme Court.

REVIVAL of old mining properties by modern methods is a subject which is engaging increased attention by mine operators. The Secretary of State reports the revival of 43 companies in California during the first six months of the year, with a total capitalization of $22,978,500. In the current issue we record the recent revival of mining at Aurora, Nevada, and detail the milling practice. Old mines, like old tailing dumps, are often worthy of investigation and many of the mines of the future will doubtless be mines of the past.

JOHNSON once said that a man ought to read as inclination leads him, for what he reads as a task will do him little good. Granting the wisdom of the remark, the inclination can yet be guided so that at the end of each year a man shall feel himself possessed of wider knowledge of every subject than he had at its beginning. There is no easier way to acquire true culture than by thoughtful reading of the best books on a wide range of topics. Engineers often rank high as golf players, stamp collectors, or the like; they might even better rank as distinguished amateurs in political economy, public finance, sanitation, public hygiene, or some other useful subject, just as Dr. James Douglas is a well known authority on the early history of New England, and Mr. H. C. Hoover the leading authority on the early history of mining.

RADIUM INVESTIGATIONS by the United States Bureau of Mines at Denver, noted in an editorial of May 30, have recently resulted in the application for patent, by Mr. Richard B. Moore, for a process for the extraction of refined radium salts. The process is reported to be in successful operation at the South Denver plant of the Bureau and will be given to the public for free use. It is stated that this government plant will be able to supply American hospitals with radium salts in the near future. While out of 972 cases treated by the Radium Institute of London in 1913 only 56 were apparently cured and 183 improved, physicians are still hopeful, and a more thorough study of the element, it is hoped, will redound to the good of humanity.

FOURTH OF JULY at Ely was celebrated by mine-rescue and first-aid contests, which were held under the auspices of the University of Nevada. The interest and enthusiasm aroused by these contests is reported as having equalled that formerly displayed in drilling contests and foot races. The 'safety first' movement, which was inaugurated in Nevada sometime ago and resulted in the organization of a state association for its advancement, is producing results and it is gratifying to note the hearty support which the mine operators are giving this movement.

WORKMEN'S COMPENSATION INSURANCE IN CALIFORNIA

As we noted last week the 'Mine Owners' Casualty Indemnity Exchange' has been formed to afford to mine operators a means of insuring themselves against terms of the 'California Workmen's Insurance and Safety Act.' We have frequently discussed this Act and the unequal manner in which it bears down upon mine operators. While there is little disposition among the latter, even in the face of what they justly feel to be unfair burdens, to question the soundness of the general principle that each industry should carry its own burdens, there is a widespread feeling that in mining, no way has been yet provided to distribute those burdens equitably.

We have had frequent conferences with the Industrial Accident Commission and can assure the mine operators that the Commission shows every disposition to afford them such relief as lies in its power. As we pointed out January 17, the funds placed at the disposal of the Commission by the legislature are inadequate to permit it to carry unlimited liability on mines, and any other insurance is unsatisfactory. It was at first hoped that it would be possible, with the friendly services of the Commission, to establish a separate fund for mine insurance on a mutual basis; the Commission doing the work involved at cost. Legal advice was, however, to the effect that any such fund, if under control of the Commission, could not be maintained in the face of any shortage in the general fund due to a catastrophe in another industry. In the end, the state must make pro-

vision permitting the Commission to offer insurance to the small operators, or the development of new mines will be greatly restricted or cease altogether. The larger operators can, and should, combine in a mutual company and carry their own risk at the same time that they establish their own inspection service, so as to permit a risk-rating system to be evolved. In the absence of any such general association, and the fact that the law itself cannot be amended until the legislature meets, indemnity exchanges seem to offer the only possible means for reducing the premiums. That the cost at present is too high is evident from a number of circumstances.

The cost now varies with the nature of the work. We have collected figures covering $5,112,870, estimated pay-rolls for 1914. The average rate paid is a trifle over 6 per cent. The greater number of mining companies are carrying their own risk. Of 71 mines reporting, 29 are insured, 27 not insured, and 15 failed to state. Of mills and smelters the figures are: reporting, 35; insured, 20; not insured, 14; not stating, 1. At the mines the total pay-roll insured amounted to $782,276; and the non-insured or not stated, $2,111,505. The average pay-roll at 58 mines amounts to $49,893. At the mills the insured pay-roll amounts to $272,034; the non-insured or not stated, $747,520. The average mill pay-roll is $29,987. By branches of mining the figures are:

	Pay-roll.	Rate.	Insurance.
Mining in general	$2,596,118	$7.86	$204,055
Hydraulic and dredging	1,382,626	5.25	73,588
Mills and smelters	1,134,126	3.15	35,725
	$5,112,870	$6.17	$313,368

It is impossible to say exactly what the real cost of the insurance is. While we have returns from a large number of companies based upon their accident rate in the past, it must be admitted that these records have not always been well kept and that past conditions no longer obtain. One notably liberal and well managed company operating two mines and with a total pay-roll of about a half million dollars, found the total cost of compensation, medical, and hospital service at one of its mines to be 2¾ per cent in 1912, 2.65 per cent in 1913, and at the other mine 1 per cent. Its officers estimate that under the new law the cost will be approximately the same. Another mine with a pay-roll of $158,179 found the cost under the Roseberry act in 1913 to be $6190, and estimates that under the new law the cost will be 2¼ times as much. Other figures might be quoted, but their variation causes hesitation in accepting them as a guide, though it is to be noted that none of them even approximate the rates asked by the insurance companies. Perhaps a better basis for figuring is an estimate made by an experienced insurance man, based upon operations in California and covering $17,000,000 in pay-rolls. Applying to the accident record covered by this pay-roll the terms of the present law, the cost of compensation was estimated at $285,000. We have had no opportunity to check these figures, but so far as data are available to us they tally. It will be noted that less than one-third of this pay-roll would produce more than the total sum in premiums, at the rates actually being charged.

Another reason for believing that California mine operators are being overcharged, is the experience that many of them are having as mine owners in Nevada. We gave the figures for the first 10 months operation of the Nevada law, in our issue of June 27. It is unnecessary to repeat, but with a base rate of 2.2 and a maximum of 3 per cent, the insurance fund is meeting all claims and building a surplus; and in Nevada the bulk of the business is with the mines. It is true that the terms of the law are not identical with that in California, and it is possible, as urged by insurance men, that adequate provision is not being made for the catastrophe risk. Time will tell as to this, but in California, so far as the workmen are concerned there is some question whether the cost of a catastrophe would be met by some of the insurance carriers. California laws give to the Insurance Commissioner limited powers, and the Industrial Accident Commission has taken the ground that as one branch of the government of the state it should not question the action of a coördinate branch in permitting an insurance company to do business within the state. Whether the insurance be good or bad, the operator is protected; though possibility of an attack upon the constitutionality of the law lies in the power under these conditions to do away with the workmen's fundamental right to compensation for injury, without his consent. That again is a problem for the future. It is only important at the moment in connection with the fact that the new form of insurance, represented by the indemnity exchange, is now available to California operators.

Under the plan of the exchange the insurance is carried mutually by the companies or individuals forming it. The rates paid in are the same as those of the regular companies and in addition notes, securities, or cash equal to an extra premium or a defined part of such a premium, are deposited with the exchange, to meet a contingent risk. From the sums so accumulated a percentage, in the case of the concern mentioned amounting to 20, is taken to cover the cost of conducting the business. Next the losses are paid, and the necessary reserve set aside to cover future payments on these losses. The remaining funds are periodically distributed in the form of dividends. The total liability of any person or company in such an exchange is limited to the amount of two annual premiums. The final cost of the iusurance is his due portion of the actual loss met by all members of the exchange, and the sum mentioned as paid for general expense. If he insures with a regular company he pays one premium and gets no refund. If he joins the exchange he risks two premiums and gets insurance at cost plus 20 per cent. Since regular companies pay that rate, at times more, to agents who solicit the business, the member of an exchange gets his insurance for cost and makes the solicitor do the work.

As is true of all institutions there are drawbacks. In the first place there has been no specific decision in California to the effect that such exchanges constitute insurance carriers so as to relieve their members of all further liability. In a few states it has been held that there is still a contingent liability, but, as always, it is needful to be careful in drawing conclusions, since the various state laws differ, as well as do the courts. In California there is an especially strong presumption in favor of the exchanges since their organization is specifically provided for by law. There is the further fact, already noted, that the Industrial Accident Commission is not disposed to go behind the fact that a company or an exchange has been authorized to do business by the insurance department of the state. As a matter of fact such exchanges are now in operation in a number of industries.

The second danger is that members of an exchange must work through a person or persons who are constituted 'attorneys in fact,' under terms of the insurance contract. These men handle the funds and conduct the business. In the case of the 'Mine Owners' Casualty Indemnity Exchange,' they are young but experienced insurance men who are in the business, properly enough, for profit. Provision is made for an advisory board of three members of the exchange which has large supervisory powers. Presumably they will be mine operators, and if the results of the exchange prove unsatisfactory they will be to blame, since the three will have a clear majority on the board. A further safeguard is the right of cancellation which is reserved to each exchange member.

Mine operators having shown no disposition to organize a mutual company to care for themselves, experienced insurance men offer to form such a company, operate it on a limited ratio of cost, and permit its members to have a majority upon what will constitute for most purposes a board of directors. This warrants investigation.

BUSINESS AND POLITICS

In a sane and conservative exposition of the relation of business to politics, Mr. F. A. Vanderlip, president of the National City Bank of New York City, in a recent address before the New York Bankers' Association, presented a statement of facts and conditions bearing on the present so-called psychological depression which sums up the present condition of business in the United States in an admirable manner. His appeal to the bankers and business men to get in closer touch with the economic and political tendencies of the day and to direct their energies more to guiding and informing rather than obstructing is most laudable.

There was a time when the outlook for business was gauged by production statistics, distribution of products and manufactures, by the state of the money market, by records of the accumulated stocks, and by the condition of credits. With such statistical data of business in hand and correlated, it was not impossible to make a fairly accurate prediction of what the future had in store for a twelvemonth. The statistics of business were a measure of the business outlook. It is almost startling to note how far from true that is today, and how important has become the adventitious factor of legislation and legislative tendencies. It is no longer possible to measure the outlook in the terms with which business men are made familiar through their daily routine. The *Congressional Record* is crowding out of its place of importance *The Financial Chronicle,* and the public is watching and waiting for executive and congressional action rather than the comptroller's abstract to measure the status of industry. Mr. Vanderlip cites as an example of this feeling on the part of the public, the fact that the attitude of mind of the Interstate Commerce Commission has become more important than the statistics of railroad traffic; the amount of our foreign trade is studied to learn the effect of changed tariff law rather than of trade tendencies. Reports of the attitude of mind of the Attorney General vie in interest with the crop predictions of the Secretary of Agriculture; investigations by bureaus, commissions, or Congress form a more important feature in gauging a market outlook than do the plans for development or expansion formulated by the executive committees of corporations.

The factors which appear uppermost in the minds of the business interests of the nation are what is going to be the effect of new legislation, what new laws are to be enacted; not what is the prospect of crops but of congressional action. It, therefore, seems reasonable that so long as the public looks with fear and trembling to the action of commissions and governing bodies, rather than to natural conditions, the present inertia will continue. Mr. Vanderlip states a belief that if business men will get themselves into a state of mind where they view conditions broadly, with a historical and social sense rather than only from their individual point of view, they will apprehend better the direction in which the whole current of political thought is flowing and will feel less impatience with the legislative movement and vastly less pessimism concerning its results.

As a result of Mr. Vanderlip's plea, a publicity committee has been appointed whose purpose will be to enlighten and direct public sentiment rather than contend with it. No good can be attained by quietly sitting by and railing at Washington. With a 900,000,000-bushel wheat crop and a statistical position of industry which should warrant a prediction for prosperity and immediate expansion, there appears to be a psychological phase to the present depression. While this condition may be intangible, it is nevertheless real; a restoration of confidence in what the future has in store and a realization that industry is not being plotted against by the executive and legislative heads of our government, while it may not be a solution of the difficulty, would undoubtedly strengthen the business position and remove some of the obstacles from the channels of progress.

GENERAL VIEW OF THE BARTLESVILLE SMELTERS, SHOWING THE NATIONAL

Zinc Smelting at Bartlesville, Oklahoma

By E. H. LESLIE

The Oklahoma gasfields mark the apparent last stand of the natural-gas zinc smelter, and while the days of such plants are by no means numbered, unless unexpected discoveries are made in this or other localities, the time is not indefinitely far off when the zinc smelting interests must abandon the present natural-gas belt and seek sites convenient to permanent fuel supplies and reasonable freight rates. At the present time the coal districts of Illinois are most favored, as they have been since the beginning of the industry in this country, but the latest zinc smelters are being erected farther east, in Ohio and western Pennsylvania.

Fuel is, of course, the keystone upon which depends the life of the smelter. At present there is no shortage of gas at Bartlesville and there are three smelters in operation; the Bartlesville Zinc Co. and the Lanyon-Starr Smelting Co., both subsidiaries of the American Metals Co., and the National Zinc Co., which is controlled by Beer, Sondheimer & Co. and E. O. Jacobsen. The future gas supply is uncertain and as a result the plants have not that stamp of permanency which characterizes the new producer smelters of the Illinois coal districts. Improvements and upkeep expenditures are kept low, since no one knows upon what day there will be no more gas and Bartlesville will follow in the footsteps of Iola. In an effort to prolong the life of the smelters, the Smelter Gas Co., a subsidiary of the American Metals Co., has been organized and, having leased large tracts of land in the vicinity of Bartlesville, is exploring this ground vigorously for new gas deposits, with some success. The gas consumption of the three smelters when in full operation amounts to 23,000,000 cu. ft. per day. The Bartlesville Zinc Co. uses 9,000,000 cu. ft., the Lanyon-Starr Smelting Co. 6,500,000 cu. ft., and the National Zinc Co. 7,500,000 cu. ft. per day. While it is impossible to say how long this consumption can be met, there is reason to believe that the end is not yet in sight and a long period of activity is anticipated.

The Bartlesville smelters are situated about one and a half miles southwest of Bartlesville. The smelter sites lie on the north side of the right-of-way of the Missouri, Kansas & Texas railway lines, from which private sidings have been laid for the unloading of ore-cars and supplies and shipment of spelter. The town of Bartlesville is 75 miles from Joplin, the centre of the zinc mining industry of the Middle West and from which the smelters in the past have received the bulk of the concentrates treated. The topography of the smelter sites is generally level, with some depressions which have been filled with retort residue and others which at the present time are being used for dumping ground and will afford dumping space for years to come.

Bartlesville No. 2 Plant

The ground plan of the Bartlesville Zinc Co.'s smelter, which is shown in the accompanying drawing, shows the arrangement of the buildings. The compactness of the plant and favorable spacing of buildings and furnaces for short hauls, with little or no available space wasted, is apparent. The general view of the plant, opposite, shows the character of the buildings and furnishes an idea as to the magnitude of the works. In addition to the standard-gage railway turn-outs, the plant has adequate narrow-gage industrial track for the handling of charges, pottery, residue, spelter, and smelter supplies.

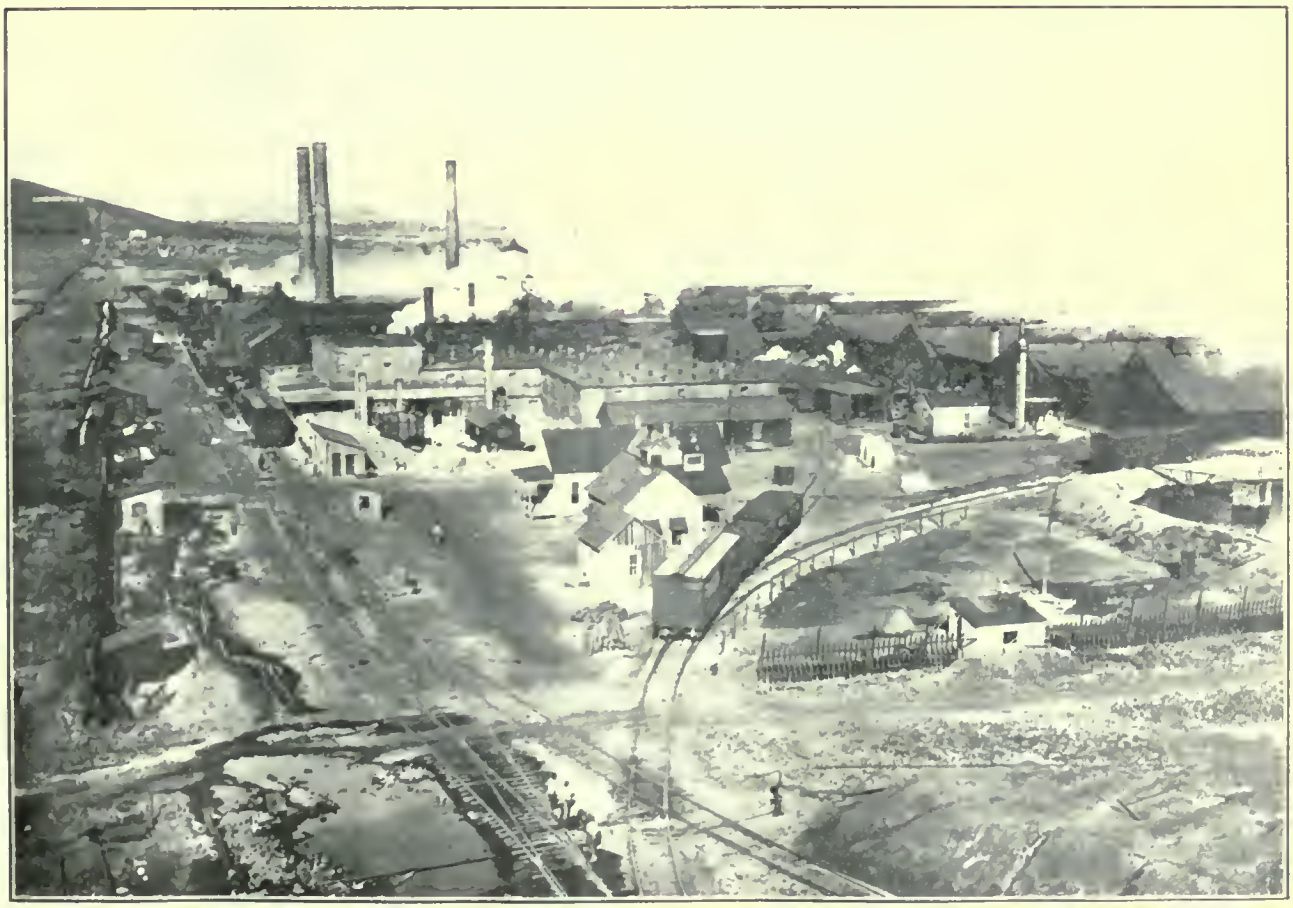
In the past the smelter was operated largely on Joplin concentrates, but at the present time the bulk of supply is a flotation product from Butte, with some Joplin, Colorado, Needles, and Mexican ore. The concentrates are received at the plant in ordinary freight cars and unloaded by hand into the receiving bins in the ore-house at the northwest corner of the property. The ore-house is divided into compartments for the storage of various grades and kinds of concentrates. The bins are flat-bottomed with wooden partitions and are underlaid with steam coils which are used for reducing the moisture in

ZINC COMPANY, LANYON STARR, AND BARTLESVILLE No. 2 PLANTS.

the concentrates as received. The bins are on the ground-level, and in removing concentrate it is necessary to shovel it into barrows, in which it is taken to the crushing and drying department.

Two circular dryers are situated in a wing of the old roaster house containing the three original furnaces, while another dryer of the same type has been installed in the new roaster house, which contains two additional furnaces. The concentrate, which is usually a mixture of Colorado and Butte ores, is fed at the centre of the dryer and moved by revolving rabbles to the periphyry where it is discharged through chutes into the boot of a bucket-elevator. The bucket-elevator discharges into a 4-mesh trommel screen, the oversize from which is returned to a pair of 24-in. rolls, while the undersize is taken by a belt-conveyor to the superimposed steel feed bins of the Zellweger roasting furnaces. The drying capacity of the smelter is not sufficient for handling the entire roaster feed, with the result that during the day shift undried concentrate is shoveled directly upon the feed end of the roasting furnaces and both drying and roasting is done by the Zellweger roasting furnaces during the day shift. The dryers and crushers are operated by a 50-hp. General Electric motor operating on a 110-volt circuit.

For roasting sulphides, five of these furnaces are



THE BARTLESVILLE No. 2 SMELTER.

used. This type of roasting furnaces has found considerable favor through the Oklahoma gas smelting district. The furnaces are of the mechanical reverberatory type with hearths 150 ft. long and 15 ft. wide. The rabbling or raking mechanism is the special feature of this type of furnace and consists of a number of V-shaped steel cups which are mounted radially on a heavy shaft with cog-wheel supports connected by wire cable with the driving machinery. The wheels rotate on tracks in wheel pits at the sides of the hearth and are sometimes protected by an apron which is suspended from the arch and thus protects the wheels and driving

end, while on the return to the feed end the charge is moved but little and only a plowing effect is obtained by the rabbles moving over the hearth. The racks, which serve as track for the support of the rabbles and cause the mechanism to move uniformly through the furnace, are air-cooled by an air-chamber below them and the rabbling mechanism is air-cooled as it passes out of either end of the furnace, where it remains for a minute and a half before the return trip through the furnace. The ends of the furnace are closed with hanging walls and sheet-iron suspended doors as shown in the halftone. The furnaces, as operated at the Bartlesville plant, will

mechanism from the intense heat of the furnace. A flash-light photograph of the interior of a Zellweger furnace at the Neodesha plant of the Granby Mining & Smelting Co. is shown opposite. This furnace is a typical Zellweger roasting furnace and the rabbling mechanism and the class of construction is seen from the illustration. The rabbling cups are fitted to collars which are mounted loosely on the shaft and a locking device holds them rigid or allows them to turn on the shaft according as to whether the passage of the rabble wheel is from the feed to the discharge or from the discharge to the feed end of the furnace.

By this means the charge is uniformly picked up by the cups, raised, turned, and moved forward as the rabbles pass through the furnace toward the discharge

treat 30 tons of concentrate per day reducing the sulphur content in the roasted product to about one per cent. The temperature of the furnaces is kept at about 1000°C. The roasted concentrate is discharged from the end of the hearth by the rabbles, which move the charge every six minutes. It falls into steel cars and is removed to steel storage bins. The furnaces are equipped with 10 gas burners on each side. The four burners nearest the feed end are ⅝ in.; these are followed by three ½-in. and three ⅜-in. burners, making 20 burners to each furnace. The rabbling mechanism is driven by a 12½-hp. General Electric motor operating on a 110-volt circuit, each furnace having an individual motor. The motors are equipped with automatic starting, stopping, and reversing device for regulating the travel of

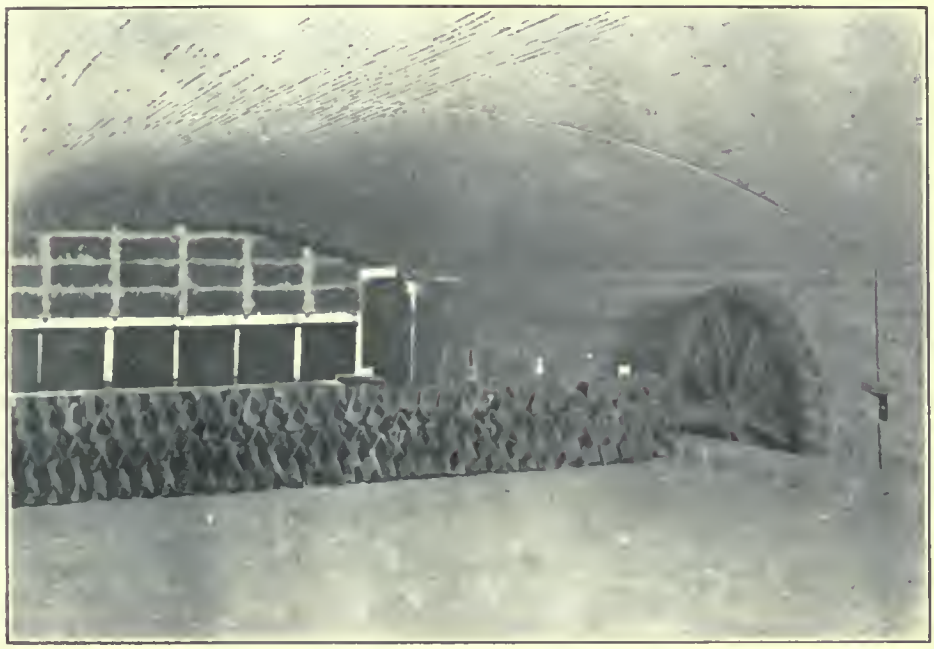
the rabbles through the furnace, a simple hydraulic device being used for this purpose. Combination tile and steel stacks discharge the furnace gases into the atmosphere. When the furnaces are being fed with dried concentrate from the superimposed bins, the feed is automatic, the gate being tripped upon each passage of the rabbles through the furnace and the feed falling directly upon the hearth.

Retort Fuel

The coal used in the mixing room is brought from the Pittsburg, Kansas, field together with some Arkansas semi-anthracite. It is delivered from the railway cars at the coal bins, which are conveniently situated with relation to the mixing house and centrally placed with reference to the furnace buildings, as shown in the plan of the plant. Here the roasted sulphide, carbonate, and fuel are mixed in a concrete mixing machine, and the mixed charge elevated to bins from which it is drawn into the charge cars and moved over the industrial tracks to the furnaces.

The original smelter plant comprised six blocks of retort furnaces, to which three additional blocks have been added. The furnaces are a modified Hegeler type 100 ft. long and adapted to natural-gas fuel. The furnaces consist of 18 sections on each side of the block, with 16 retorts to the section in four rows, making 288 retorts to the side, and 576 retorts to the block. The plant, therefore, comprises 5184 retorts in the 9 blocks of furnaces. Air and gas is admitted at the front of the furnaces at each section, a practice which in some of the more modern natural-gas furnaces has been replaced by using a 'blow-box' at each half-section. The furnaces are of the cellar type. The retorts used are 50 by 8^3_4 inches inside dimension and are made, together with the condensers, at a pottery on the grounds. As has come to be standard practice in the United States, no prolongs are employed. The average life of the retorts at this plant is about 30 days. Air for the furnaces is supplied by a blower in the engine room and conducted to the furnace blocks through a galvanized iron pipe-line and distribution system. Under present operating conditions there is charged from 14,500 to 16,000 lb. of roasted ore to the side per day or about 150 tons of raw concentrate for the entire plant. The extraction of the zinc is about 85% of the charge assay.

The furnaces are about seven years old and in a good state of preservation. Blue powder is added to the charge in the last two sections of each block and a temperature of about 1400° C. is maintained. About three hours are occupied in charging the retorts, from 4 to 7 a.m. The first draw is made at 3 p.m., the second at 11:30 p.m., and the last about 4 a.m. The result of a day's run is about 115 slabs of spelter to the side, the first draw producing about 35 slabs, the second 65, and the last 15. The first metal drawn, being distilled at the lowest temperature, is the purest, and is cast as 'extra select' in 56-lb. molds. The regular run of the furnaces is cast in 60-lb. molds. The retorts are drawn into a 360-lb. ladle suspended from a crane in a movable carriage, which ladle is swung under the condensers and operated by a hand winch. The oxide or 'blue powder' is skimmed off and shoveled aside for re-treatment.



INTERIOR OF A ZELLWEGER ROASTING FURNACE.

During drawing operations the drawman is protected by a shield on the draw carriage from the heat of the furnace. After the last draw, the residue is removed from the retorts and falling through a chute in front of the retorts is collected in industrial cars or pans below the furnace. Steam is used for cleaning the retorts, the water being immediately converted into steam upon entering the retort. The water-line and hose connections are in front of each side. Any slag adhering to the retorts is removed by scrapers. In cleaning the retorts the man operating the hose is protected by a shield which is suspended from a rail on rollers and is easily moved along the furnace. Twenty men are employed per day on each block.

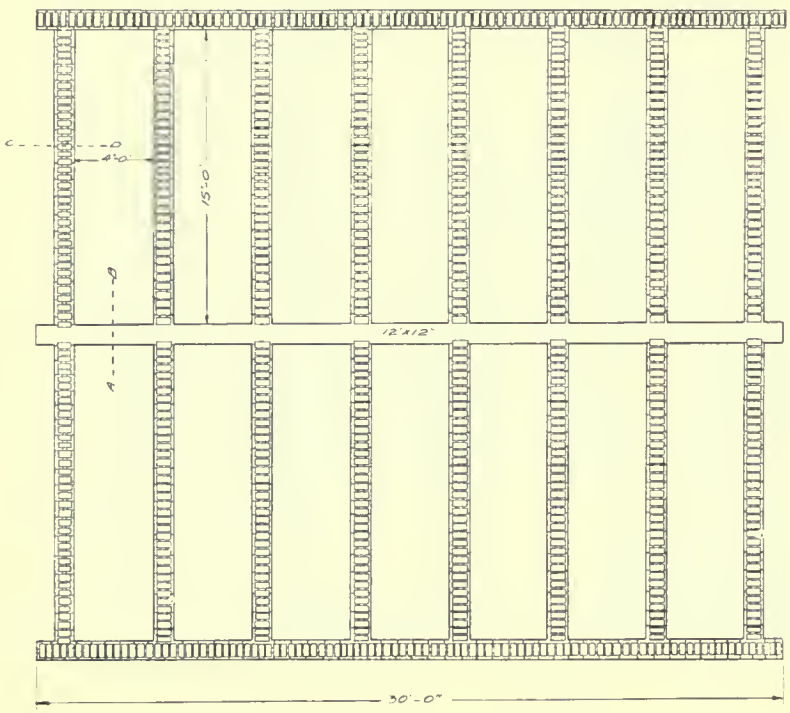
Treatment of Retort Residue

The treatment of retort residue presents some interesting features which have been developed at this smelter as a result of the treatment of the Butte flotation concentrate. In that the residue contains silver in commercial quantities, a large amount of experimental work was necessary to develop the best method of recovering the silver and it has resulted in the 'clinkering

proeess' by which a blast-furnace material is made at the plant and shipped to Colorado smelters. The process consists in reducing the carbon content, which is upward of 30%, and the formation of clinker.

Construction of Heaps

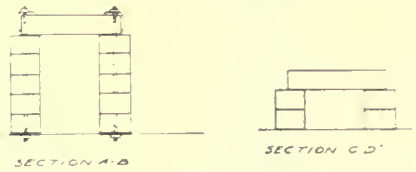
The residue is removed from the furnaces in steel industrial cars and run out over an elevated structure as shown in the halftone to a site to the north of the smelter, where it is dumped and shaped into roasting heaps. In the building of these heaps a bed of residue 2 ft. thick is spread out into a square of from 20 to 30 ft. on a side, and upon this bed, brick-work air channels are constructed. A plan and sections are shown in the



PLAN OF BRICK-WORK FOR CLINKERING-HEAPS.

accompanying figures. One main air channel is laid through the centre of the bed and this channel is banked with dirt to prevent clinker from adhering to brick-work. From the main channel, branch channels are constructed at right angles extending to the edges of the heap. Eight of these branch channels are laid to allow the air to escape and be evenly distributed, thereby producing a uniform blowing effect throughout the heap. The ends of these branch channels are connected in the large heaps as shown in the plan. The main channel is connected by pipe with the main air-distribution pipe and this is connected with a blower which supplies air for all of the heaps. When the brick-work has been completed it is covered with residue, the air is admitted, and the heap is fired. The heap is then added to until a height of about six feet is reached and it contains about 400 tons of residue. The roasting or burning process is kept up for approximately 40 days, when the pile will be reduced to less than one-half its original size, the carbon reduced to almost nothing and a mass of clinker bearing silver results. This clinker is then cooled, broken, the brick channels removed, and the product shipped to Colorado furnaces.

The pottery plant at which the retorts and condensers for the Company's use are manufactured is equipped with a Mehler retort press, and pug-mill, an augur condenser machine, and two small Ft. Scott pug-mills for pugging condenser materials. The crushing machinery consists of one 12-in. Blake crusher, one set of 24-in. and one set of 16-in. rolls, and screens. The retort material is ground to 5 mesh. St. Louis clay is used for retorts while the condensers are manufactured from a 1 to 1 mixture of clay and old retorts. The clay is unloaded from freight cars into the clay-



bins, where it is weathered from three to six months. After the first pugging it is cut into short cylinders as it comes from the pug-mill and again stacked for about a week, when it is given the final pugging and put into the retort press. The retorts are inspected as they come from the press and sent to the drying rooms, which are steam heated. They are then removed from the drying rooms as the furnaces demand, placed upon industrial cars, and taken to the furnaces where they are finished in the annealing ovens, there being one annealing oven to each two blocks of furnaces.

The power-plant, which adjoins the pottery building, is equipped with a 250-hp. Corliss engine with belted generators, a 150-hp. Chase compound, and a 120-ft. Garden City blower to supply air for the retort furnaces. Natural gas is used for fuel under the boilers. There is also a fire pump with pipe connections to all departments of the plant. The water supply is brought through a pipeline from Sand creek, which is a mile and a half southwest. An earth-bank reservoir 250 by 100 by 10 ft. deep serves as a reserve water storage at the smelter. There is also a 10,000-gal. steel tank for the smelter supply, the water being pumped to this tank from the earth reservoir.

The plant equipment includes about two and a half miles of narrow-gage industrial track for the handling of smelter products and a mile of standard-gage railway sidings for the receiving of smelter materials and shipment of spelter. A laboratory building is fitted with all of the equipment necessary for making industrial analyses and determinations in connection with zinc smelting. There are also machine and blacksmith shops, carpenter shops, lime house, wash rooms, and offices on the smelter site.

Due largely to the efforts of the present manager, Archibald Jones, the smelter, after a somewhat dis-

couraging beginning, is at present being successfully operated, and the development of the treatment of Butte flotation residues has constituted one improvement in the smelting of zinc concentrate.

Dust Prevention on the Rand

A simple but seemingly effective process for preventing dust-blowing from dumps has been placed in active operation at the Ferreira Deep. The originator of the process is F. L. Bosqui, who describes the process as follows: It consists of spraying the surface of the dumps with the slime residue in the condition in which it is ordinarily pumped to the slime dam and mixed with about 100 lb. of salt per ton of two parts water to one of slime pulp. The hygroscopic properties of the salt prevent the crust from drying and cracking. It is estimated that it might be necessary to renew this coating three or four times a year at insignificant cost. The spraying plant consists of a 40-ton cone-bottom agitator to which the residue slime stream is diverted as required. From this tank the pulp is forced by means of a triplex Gould pump into a 4-in. distributing main provided with hose taps at suitable points. The pulp is sprayed on the dump by means of a 4-in. hose and nozzle, the stream issuing from the nozzle at about 40 lb. pressure. So far the system has proved extremely simple and inexpensive as well as effective. It is too early to obtain definite figures as regards cost, salt consumption, etc., as the proportion of salt, the thickness of slime pulp, and other details will necessarily be modified in accordance with experience.

The effect of the spraying is to give the dump a thin crust. The peculiarity of the crust is that it is not so brittle as might be expected. There is a degree of plasticity about it which is renewed by the moisture in the air. The hygroscopic or moisture-absorbing property of the salt in the spraying mixture prevents the crust from drying and cracking. It only remains to test the capability of the crust to resist the disintegrating influence of the high winter winds. Should they prove powerless to rob the process of its efficacy, a great boon will have been conferred upon the mine dwellers of the Rand. An estimate of the cost of spraying the dump places it at the modest figure of a penny per 100 sq. ft., or even less.

The hose is easily manipulated by one or two natives who can spray at a rate of considerably over an acre per hour, consequently the time taken to spray a whole dump, once the equipment is erected, would be in most cases under a day, and in no case would it exceed two days.

The idea of adding brine to the slime was suggested by F. J. Trump, manager of the Ferreira Deep, who pointed out that salt is used in some of the colliery districts in England for laying dust on roads. The installation at the Ferreira Deep cost under £1000. The credit for being the first to apply the spray treatment for the prevention of dump dust is due to the East Rand Proprietary Mines, which has already covered the Driefontein dump with a coating of *vlei* mud, which has proved very effective, but such mud is not everywhere available, and, in any event, the use of current slime which Mr. Bosqui has installed is cheaper, simpler, and more likely to be universally adopted.—*Capetown Times.*

THE WORKS of the Hydro-Electric Power & Metallurgical Co. have been acquired by the Tasmanian Government. Financial troubles led to this end. Good progress has been made with the pipe-lines and power-plant, and within a year there will be 85,000 hp. available for mines and manufacturing plants.

MINERAL PRODUCTION of New South Wales for the first quarter of 1914 was worth £2,754,999, an increase of £467,162 over the same period of last year. Coal and silver-lead exports showed a large increase.

Siderite and Sulphides in Leadville Ore Deposits

By PHILIP ARGALL

Siderite, though once of considerable economic importance, is now the least valuable of the iron ores. Even manganiferous siderite, at one time in great demand for the manufacture of spiegeleisen, has now no economic value in the West. Genetically considered, siderite is perhaps the more important of the sedimentary iron ores, most of which have been precipitated as carbonates and, through chemical and other processes, rearranged or redeposited chiefly as hematite. Much of the Lake Superior iron ore is now considered to have had such origin.[1] The hematite ore of Breece Hill iron mine, Leadville, is in all probability derived from siderite, which is plentiful at depth even now in that locality, and recently has been reported in great abundance in the Hopemore mine.

Siderite (carbonate of iron) has long been known as an important mineral of Leadville replacement deposits in the blue limestone horizon, particularly in association with the primary sulphides, and in fissures and solution cavities. Over 25 years ago I collected specimens from the walls of watercourses in the La Plata mine, partly filled with manganese oxide, and reached the conclusion that this oxide was in great part, if not wholly, derived from the oxidation of siderite. Last May I picked up specimens from the dump of the adjoining Stevens mine showing a crust of manganiferous iron oxide attached to partly oxidized siderite. A casual examination of several mine dumps a few days later showed siderite in every one, resulting in a nice collection of specimens, some pyritic, but mostly typical siderites comparatively free from oxidation. The dumps yielding siderite are the Stevens, Colonel Sellers, A. Y. & Minnie, Colorado No. 2 (Louisville group), R. A. M. (Mikado group), the Penrose (down-town mines), the Wolftone, the El Paso, the Jamie Lee, and the Fitzhugh. I had previously collected specimens from the workings of the Resurrection, Moyer, Tucson, Silver Cord, and Maid of Erin mines.

Distribution of Siderite

The list, covering two miles in one direction and almost five in another, from the Resurrection to the Penrose, is ample to show the wide distribution of siderite at Leadville. While I examined no other dumps, excepting those of the principal downtown mines, there is little reason to doubt the occurrence of siderite in all the mines that have penetrated the oxidized zone, while in the white limestone horizon, the siderite replacement deposits with their associated lead and zinc ores, are second only in importance and extent to the sulphide replacements in the blue limestone horizon; judging by the last few years' development in the Tucson mine of the Iron Silver Mining Co. and of the Maid of Erin mines.

I believe that *sedimentary siderite* with its carbonaceous and organic impurities should be differentiated from the siderite deposited in fissure veins and in replacements therefrom, herein called *vein siderite*. Both varieties contain manganese chiefly as carbonate; particularly vein siderite, which invariably contains a much higher proportion of manganese than does sedimentary siderite. It may be permissible in discussing the difference between sedimentary siderite and vein siderite, briefly to review some of the important siderite veins, including that peculiar class of silver-lead-zinc veins in which siderite forms the principal gangue; then to compare chemical analyses of vein siderite with those of sedimentary origin.

European Siderite Veins

The great Perran Iron lode, Cornwall, England, occurs in Devonian clay slate intruded by granite porphyry dikes. The vein averages about 50 ft. in width and is in places filled with massive siderite carrying 10 to 15% manganese. The outcrop has been extensively worked for limonite, and much siderite was mined in the 'seventies' from the deeper workings. Because of the decline in the price of iron and increase in silica in the ore, it could not be profitably sold as 'spiegel' ore in 1880, when I had charge of the principal mine on the lode. The vein bore evidence of reopening, and between the shoots of massive siderite a breccia of zinc-blende occurred. In the Duchy Peru mine, the angular pieces varying from a few pounds weight to several tons, were imbedded in decomposed clay slate, and cemented and seamed with siderite. The blende breccia was profitably worked for several years with a production varying from 500 to 900 tons per month of 38 to 42% zinc content. Rich veinlets of argentiferous galena occurred in places, but apart from stray crystals of galena and sphalerite the siderite was free from zinc, lead, and silver. Near a granite porphyry dike ('elvan') a large deposit of fine grained sphalerite occurred in a siderite gangue. The difficulty in separating these minerals by water concentration led to my first experiments with magnetic separation (in 1881).

The vein in the siderite shoots was full of watercourses and oval solution cavities. One of them extended two levels in height and was used for a ladderway. The vein was extremely wet, the flow at the Duchy Peru mine varying from 600 to 1000 gal. per minute, depending on the season. It all came from the bottom of the mine. The iron ore sequence is approximately as follows: limonite to 60 ft.; siderite, 60 to 360 ft.;

[1] Ries, Heinrich, 'Economic Geology,' 1910, p. 370.

silicious siderite, 360 to 450 ft.; and at 480 ft., the deepest point reached, the vein was filled with quartz and siderite, the latter constituting only about 20% of the whole.

In Brendon Hills, Somerset, England, a series of irregular siderite veins occur in slaty rocks of middle Devonian age. The veins extend over a distance of five miles, with a maximum aggregate of 27 ft. in thickness. The siderite carries 13 to 14% manganese peroxide. The brown iron of the outcrops has been mined from a very early date, while siderite has in recent times been extensively mined for 'spiegel' ore. Quartz is associated with the siderite usually as separate lenses in the veins.[2] Lead or zinc does not occur in any appreciable quantity in the veins.

Siderite in England and Germany

In numerous lead mines in the North of England in Carboniferous limestones, such as those of Allenheads for example, siderite occurs as a gangue accompanying the galena not only in the vein fissures but also in 'flats' or replacement deposits in favorable limestone beds. Siderite is of common occurrence on the European continent both in massive veins and as the principal gangue, accompanying zinc-lead ores. Suffice it to mention the Stahlberg Müsen, where a nearly vertical vein enclosed in lower Devonian clay slate has been worked since 1313. This mass of siderite is about 75 ft. thick, nearly 500 ft. long, and proved to a depth of about 800 ft.[3] The Luise mine, near Horhausen, in which sphalerite, galena, and copper minerals occur in the vein alongside siderite, is noteworthy in that in it a basaltic intrusion changed the siderite into magnetite. The siderite lode of the Friedrich and Esingarten mines of the Hamm district, which also contain galena, sphalerite, chalcopyrite, and bornite, as well as antimony and bismuth minerals,[4] may also be cited.

J. Arthur Philips[5] calls attention to the import of manganiferous iron ore into England from limestone districts producing lead ore, where it probably represents the superficial alteration of manganiferous spathose ore. He mentions Almeris and Porman, near Cartagenia, where there is a large export, Laurium in Greece, and other localities. The ore, he states, varies between 25 and 35% of iron and of manganese.

American Siderite Veins

Siderite silver-lead veins in North America are well represented by the Slocan series in British Columbia and the Wardner deposits in the Coeur d'Alene, Idaho. The Slocan rocks are clay slates and limestone beds of possibly pre-Cambrian age; this formation is intruded by granite, quartz porphyry, and lampropyric dikes. The fissure veins usually carry rich silver-lead ore associated with siderite and quartz, the latter predominating in depth. Siderite was deposited throughout the whole vein-forming period, being often the first mineral deposited on the vein walls. It also occurs as alternating seams with galena and sphalerite in the vein filling, as the cementing material in brecciated zones, and lastly, as crystals deposited on galena crystals, marking the last mineral deposition in the fissures.

Selected specimens of siderite from the Slocan silver-lead veins gave the following approximate composition:[6]

	Per cent.	Per cent.	Per cent.
Fe CO_3	58.88	62.31	36.53
Mn CO_3	27.48	26.12	55.52
Mg CO_3	11.59	11.57*	7.95*
Ca CO_3	2.05		

*By difference.

The siderite is free from zinc, though deposited in veins with sphalerite. It is also free from silver, copper, and lead as molecular constituents. However, grains of galena and sphalerite occur in all but the purest specimens. Tetrahedrite or Freibergite is the chief silver-bearing mineral. It is invariably associated with galena and often contains 2000 oz. silver per ton. The Slocan siderite, usually forming the bulk of the vein material, being free from precious metals and from zinc, becomes a true gangue in these silver-lead veins. Quartz forms the remaining gangue and is scarce in the upper reaches of the veins, but predominates in depth.

Coeur d'Alene Veins

The silver, lead, and siderite veins of the Coeur d'Alene district, Idaho, are of great economic importance, furnishing as they do nearly one-third of the lead produced in the United States. The country rock is sericitic quartzite of pre-Cambrian age, and the ores were formed chiefly by replacement along tight shear planes. It is believed the siderite developed first, replacing both the quartz grain and the sericitic cement. According to F. L. Ransome,[7] siderite is the most abundant and characteristic gangue mineral of the district. He writes: "Its presence as a replacement of quartzite constitutes a striking mineralogical feature of the ore. In fact, the deposits in this respect are unique among the known orebodies of the world." He gives no chemical analysis of this important vein mineral. The deposits are unusual because siderite forms so large a proportion of the gangue and because siderite replaces quartzite. Both phenomena are common at Leadville, but perhaps on a smaller scale so far as quartzite replacement is concerned. Mr. Ransome, describing the typical Coeur d'Alene deposit, states: "the siderite is massive, the ordinary gangue of the Bunker Hill &

Sullivan mines, for example, being a pale brown, fine grained aggregate of siderite not always distinguishable at a casual glance from the quartzite, which it has in part replaced. In the vicinity of the orebodies all gradations can be observed between nearly pure massive siderite and a usually somewhat sericitic quartzite." Coarsely crystalline siderite, he states, is comparatively rare, confined to the filling of open spaces or diaclases. Mr. Calkins observes (page 97): "That although siderite has a much wider distribution than the ores, yet it is most abundant where the rocks have been folded and fissured." A sample of comparatively clean siderite from the Bunker Hill & Sullivan mines,

FIG. 1. SIDERITE CRYSTALS ON SULPHIDES FROM IRON MASK MINE, RED CLIFF, COLORADO. 1, GALENA; 2, PYRITE; 3, CRYSTALLINE ZINCBLENDE AND GALENA.

obtained through the courtesy of Stanly A. Easton, assayed 38.8% iron, 4.5% manganese, and 0.5 oz. in silver, with only 4.8% insoluble. It contained no lead, but showed some fine specks of disseminated sulphide.

In Colorado there is a great belt of intrusive porphyry, of late Cretaceous age, which extends almost 100 miles in a general southwesterly direction from the gold-telluride district of Boulder county through the gold district of Gilpin county, the gold, silver, lead, and zinc district of Clear Creek county, the mining districts of Montezuma, Kokomo, Breckenridge, Alma, Leadville, Red Cliff, and Aspen. These intrusions, while not continuous, may be said to reach their greatest development in the mining districts noted, principally at Leadville and probably least at Montezuma. This belt of porphyry intrusion closely circumscribes the largest and richest silver, lead, zinc, and iron sulphide deposits so far developed in Colorado. Over the greater part of this mineral belt, varying from 10 to 15 miles in width, siderite is a characteristic vein mineral. This is particularly true of those veins and deposits carrying silver, lead, and zinc sulphides and extending from Silver Plume to Aspen. They reach their largest development so far known, with the maximum porphyry intrusion, namely at Leadville. Here the lower sedimentaries are seamed with fissures and extensive replacement deposits of vein siderite, associated as gangue with mixed sulphide ores—galena, zincblende, and pyrite.

Siderite has been described in the U. S. Geological Survey reports as occurring in the mining districts noted. Spurr and Garrey make frequent mention of vein siderite in their description of the Georgetown quadrangle.[8] Their figures 86 and 95 are instructive, showing siderite as the first incrustation on the fissure walls. Siderite is also described as one of the last minerals "coating all other crystals." The Colorado Geological Survey chronicles the occurrence of siderite in the Montezuma veins.[9] Siderite is a common mineral in the replacement deposits at Red Cliff, and its occurrence has been noted at Aspen by Mr. Spurr. Fig. 1 shows siderite crystals on sulphides of iron, lead, and zinc taken from wall of a watercourse in the blue limestone replacement deposit, Iron Mask mine, Red Cliff, Colorado, by courtesy of Mr. Hanington, general manager. The siderite crystals covering the galena, pyrite, and blende are the finest I have seen. Siderite, in smaller crystals, occurs all through the specimen and on the back, which is mostly pyrite.

SIDERITE IN LEADVILLE DISTRICT

All the massive Leadville siderite I have tested is of the vein variety. That is to say, it is manganiferous. It also contains 10 to 30% silica. Part of the manganese or iron is possibly present as silicate. A few analyses of vein siderite are quoted below for comparison with sedimentary siderite, taking iron, manganese, lime, and insoluble as a basis:

No. 12—J. J. Singewald, 'Report on the Iron Ores of Maryland.' Maryland Geol. & Econ. Surv., Vol. 9, Part 3 (1911).

Excluding No. 13, which is only one-third siderite, the remaining 14 samples of vein siderite average 13.44% manganese, against an average of less than 1% manganese in the 12 samples of sedimentary siderite. The computed averages are:

	Iron.	Manganese.	CaO.	Insoluble.
	%	%	%	%
Vein siderite	27.30	13.44	0.82	9.48
Sedimentary	31.70	0.89	6.36	14.92

The vein siderites not only carry a higher combined metal content, 40.7 against 32.6%, but also contain 5.5% less alkaline carbonate and 4.5% less insoluble residue; yet the manganese is the most conspicuous difference. In comparing the iron and manganese content of vein and sedimentary siderites, note that the ultimate source of both metals is the igneous rocks of the earth's crust in which iron and manganese occur in the proportion of approximately 60 parts of iron to 1 of manganese. The proportion of these metals in the above analyses is in the ratio of 36 iron to 1 of manganese in the sedimentary siderites, against 2.03 parts iron to 1 of manganese in the vein siderites. The metals, however, have not only a different solubility ratio, but also act differently in their precipitation from solution through what I shall call surface agencies, to differentiate between the deposition of siderite in lakes, bogs, and amid carbonaceous sediment, marine or otherwise, and the deposition of siderite in mineral veins.

SOLUBILITY OF MANGANESE

According to E. C. Sullivan, manganese in rocks is dissolved more easily than iron, by either carbonated water or dilute sulphuric acid.[10] F. P. Dunnington[11] showed that an acid solution of ferrous sulphate dissolves manganese from the carbonate as sulphate, with the separation of ferric sulphate and limonite. Calcium carbonate precipitates the iron, but the manganese requires access of air. The metals, therefore, may be dissolved from rocks simultaneously by the same reagent, but for reasons stated are not usually redeposited together. C. R. Fresenius,[12] from his studies of the warm springs of Wiesbaden, showed that the manganese in these waters remains in solution as carbonate much longer than the iron and is finally laid down as a carbonate, hence the manganese salt is more stable in solution and is carried farther. Through some of the foregoing reactions, manganese is partly separated from iron and is perhaps redeposited as beds of carbonate, or as a local precipitate enriching in manganese certain localities in the sedimentaries.

Thomas and MacAlester,[13] while hesitating to put forward any trustworthy example of precipitated beds of manganese carbonate, cite Barmouth in Merionethshire as having two distinct horizons containing well marked beds. They also state that manganese carbonate exists as an original deposit in the Devonian beds of the Pyrenees, in the Oligocene of Mähren, and in other localities.

Vein Siderite

The condition of solution and deposition is here entirely different. The circulating solutions are presumably strongly alkaline, sulphuretted under high pressure, and doubtless charged with CO_2. They are powerful solvents of iron and manganese minerals. That they readily dissolve silica is clearly shown in the extensive replacement of quartzite in the Coeur d'Alene and to a less extent in Leadville, where the quartzite adjoining the fissures and solution cavities between the ninth and tenth levels in the Tucson mine has been reported as reduced to a soft sandstone by removal of the silicious matrix between the quartz grains, and fine galena and blende crystals had been deposited in the interstitial spaces in the altered quartzite of the lower Cambrian horizon.[14] Further up in the quartzite the same solution that dissolved the matrix from between the quartz grains also partly filled the interstitial spaces with siderite and mixed sulphides, while the ore crust lining the solution cavities often shows siderite as the first mineral deposited in the sericitized quartz matrix, and also the last mineral formed, coating the penultimate crystals, usually of galena, with a growth of crystalline siderite.

Moreover, these irregular fissures and meandering solution cavities in the Cambrian quartzite, with their very rich gold and silver ores, are not confined to Leadville. They are common in Red Cliff and elsewhere along the 'great mineral belt' of Colorado, and are evidently produced by the same agency—hot alkaline solutions under pressure, charged with CO_2, sulphides, and ferrous iron, perhaps poor in silica content and dissolving silica in the quartzites with avidity, forming silicious carbonate and sulphide of iron replacement deposits in the Silurian limestones above, and to some extent in the Carboniferous limestone.

Selective Mining of Orebodies

By DOUGLAS WATERMAN

The question of what grade of ore will give the maximum profit when mined and treated is of paramount importance at every mine, and is an ever present problem; beginning with the inception of the enterprise and continuing throughout the whole life of the mine. The owner or shareholder usually decides whether the profits shall be won from a large tonnage of ore yielding a narrow margin of profit over a long term of years, or from a smaller tonnage of selected ore requiring a smaller capital outlay and giving quicker returns, but leaving ore in the mine. It is the business of the engineer to set before his clients the possibilities of the property for producing the greatest net profit for any capital outlay, and to define the limits within which the mine is capable of producing a constant tonnage.

Factors Influencing Output

This requires a careful study of the ore deposits to determine the width and mode of occurrence of the various grades of ore; the rate at which it is possible to carry on development; the available labor supply and its producing capacity; and the future prospects; all of which have a direct bearing on the output. The mill should be of a capacity to treat the output of ore of the grade decided upon without crowding the mine, which must run at a steady pace and according to a definite plan, or innumerable difficulties will arise. The effect of increased or diminished tonnage on the costs is of vital importance. An analysis of their relation presents some interesting facts which I shall endeavor to bring out in this paper.

For the purpose of illustration I have been fortunate not only in securing actual costs of operation over a full year, but also on a variation in tonnage ranging from 6400 to 11,000 tons. These costs are grouped under three headings: fixed charges, mining, and treatment, including tailing loss. The total cost represents the value the ore must have in order to meet all operating expenses. The cost of the various operations of mining and treatment necessarily varies from month to month even with the same tonnage, owing to renewals and repairs which must be charged to current expenses. In order to arrive at a representative cost for any tonnage, the monthly costs were plotted as shown in Fig. 1. If a straight line is drawn through the average cost for the year and adjusted so that there is a balance between high and low costs on either side of the line, it should represent the true average for any given tonnage. This method was pursued with each separate item of cost, the results being as in the table opposite.

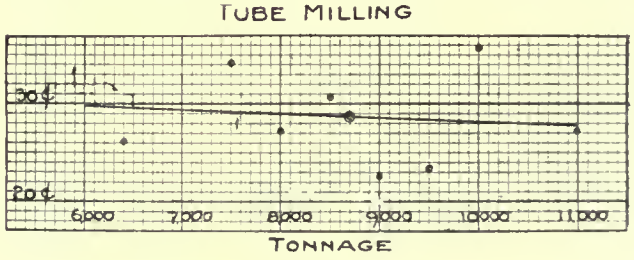

Fig. 1.

These tabulated costs were then plotted in the form of curves shown in Fig. 2. While the figures are based on results obtained from treating tonnages ranging between 6400 and 11,000, the curves may be readily extended, as has been done in this case. The curve representing fixed charges may be obtained by dividing the total cost for the year by the total tonnage, that is

to say, 12 times the rated tonnage, whether it be 4000 or 16,000 tons. The curves representing mining and treatment charges, being nearly straight lines, may be extended without danger of serious error. This graphic representation gives a comprehensive idea of the effect of tonnage on the costs, and may be employed in solving many problems in mining. In the following illustrations in the use of the curves, let it be assumed for the sake of convenience that neither profit nor loss is to result from the operations, and that the normal capacity of the mill is 10,000 tons. Then the following conclusions may be drawn.

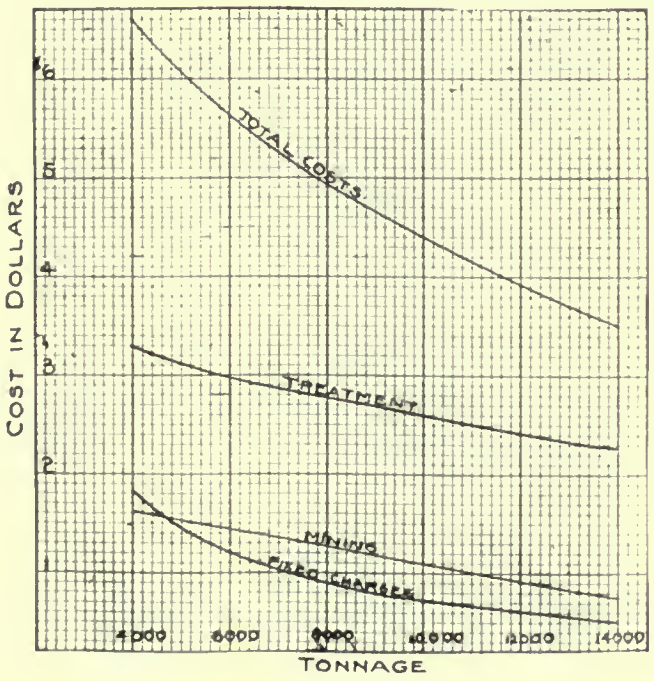

FIG. 2.

EXAMPLES

For example, if there is 4000 tons of available ore monthly which if treated alone will just pay expenses, what grade of ore may be added to bring the mill up to full capacity without changing results?

Treating 4000 tons alone the cost—from the diagram would be $6.70 per ton, or a total of $26,000; but if 6000 is added, the cost is $4.40, or a total of $44,000. The difference between these two amounts is $17,160; that is to say, allowing $6.70 for treating the first 4000 tons, it would cost only $17,160 to treat an additional 6000 tons, or $2.86 per ton. In other words, of this 6000 tons, all ore of a grade of over $2.86 would give a profit.

The following are various combinations illustrating the example:

4,000 tons at $6.70	$26,800
6,000 tons at 2.86	17,160
10,000 tons at 4.40	$44,000

5,000 tons at $6.10	$30,500
5,000 tons at 2.70	13,500
10,000 tons at 4.40	$44,000
6,000 tons at $5.65	$33,900
4,000 tons at 2.53	10,120
10,000 tons at 4.40	$44,000

These results may be applied to actual mining operations in the following manner: There are perhaps stopes on the lower levels that will produce 4000 tons of ore per month and no more, while there is a large reserve in the levels above that will average $3. If treated alone, the low-grade ore will show a loss of $1.40 per ton on a 10,000-ton basis. The high-grade ore, if treated alone, will give a profit of $0.30 per ton, or $1200 per month. Combining the two in the proportion of 4000 and 6000 tons, results in a profit of $2000 per month.

This brings out the point already mentioned, that the mine must be run according to a definite plan, otherwise the stoping of the high-grade ore is bound at some time to get ahead of development, leaving the mine with nothing but the low-grade ore, which, if treated alone, will result in a loss.

As another example, suppose there is 5000 tons of ore obtainable monthly from the mine that will just pay expenses if treated alone, what grade of dump-rock costing 10 cents for hauling, may be added to bring the mill up to full capacity and still pay expenses?

Referring to the diagram, on a 10,000-ton basis the mining cost is $1.10, so that $1 per ton is saved on the mining charge for the 5000 tons of dump-rock treated, or 50 cents on the whole tonnage.

5,000 tons of ore at $6.10	$30,500
5,000 tons dump-rock at $1.70	8,500
10,000 tons at $3.39	$39,000

Various other problems may be solved in a similar manner; as, for instance, the treatment of tailing in combination with the run-of-mine ore. In such cases, allowance must be made not only in the item of mining, but in the crushing and stamping as well, although in all probability there will be an added consumption of lime to neutralize the acid in the tailing, and perhaps a greater cyanide consumption; but these are matters to be decided by experiment.

It will be noted that the value the low-grade ore must have to pay expenses varies with the tonnage, and also that in this illustration the critical point is in the neighborhood of $2.70. It will result in an actual loss to treat any ore much below this figure.

As it is difficult to secure from month to month the exact quantity and grade of ore desired, especially where the deposit is irregular, it would be well to set a limit on the permissible grade of ore somewhat higher than the theoretical—in this case say at $3. This could be adjusted to suit conditions as indicated by observations over a period of time.

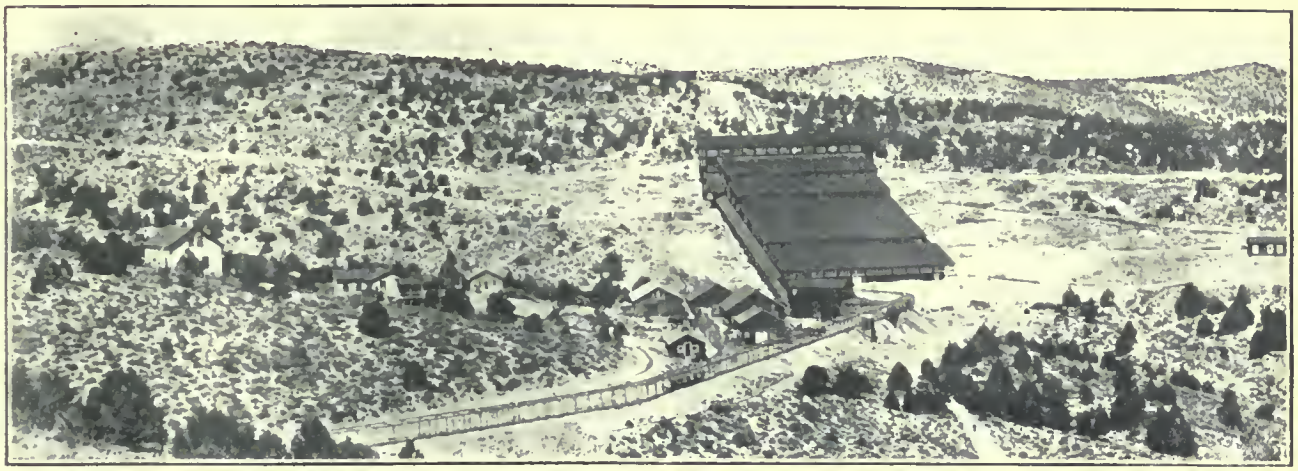
It is a mistake to think that the bullion output of a mine is any indication of whether it is being worked at its best advantage. The manager may call for 4000 tons of $7 ore. The stopes in this particular month can produce 3000 tons of $9 ore, so the miner stopes a little wider and adds 1000 tons of $1, still keeping the average at $7, but at an actual loss to the mine of from $1300 to $1700. This emphasizes the necessity for careful sampling and direction underground.

In these examples a maximum tonnage of 10,000 tons has been considered. Cases may arise in which it will be more profitable to run the mill at less than its full capacity. Where the tonnage is reduced to three-quarters or one-half its full capacity it may be advantageous, instead of running a part of the stamps the full 24 hours, to run the full number for 12 or 18 hours, and thus effect a saving in power and the labor of one shift. And if the mine is incapable of supplying the demands of the mill, why not build a smaller mill in the first place? This is where there is the greatest need for the judgment of an engineer.

Mining in Spain

Mining companies in Spain totaled 22,463 at the last census. The mineral riches of the country furnish one of its chief hopes of future prosperity. The surface areas of the workings already open cover nearly 1,000,000 hectares, or about 2,500,000 acres, an increase in area of over 25% during the last decade. In the same time the output of coal, iron, and copper have increased, while that of lead has remained about stationary. The chief provinces where mining as an industry is in the front rank are Huelva, Oviedo, Murcia, Viscaya, Jaen, Ciudad Real, Cordoba, Santander, Badajoz, Almeria, and Leon. These provinces account for 90% of the output of minerals of the peninsula. Copper predominates in the Huelva district, quicksilver in Ciudad Real, and anthracite in Cordoba. Viscaya furnishes 30% of the entire iron production, Murcia 5%, and Almeria 2%. Coal leads in Oviedo, Cordoba, and Leon, salt in Alicante and Cadiz, lead in Ciudad Real and Cordoba, zinc in Santander and Murcia, lignite in Teruil, silver in Guadalajara, manganese in Oviedo, asphalt in Alava, and antimony in Leon. As a corollary to the Spanish mining industry, what is technically known as the 'transformation branch' has made even a more remarkable advance of late than the extraction of ore. During the past 10 years the production of coke has been doubled, and iron and steel likewise; silver smelted has increased 50%, cement 150%, mercury 30%, asphalt 200%, pig iron 300%, and patent fuel 35 per cent.—*Daily Consular Report.*

MINERAL PRODUCTION of Queensland, Australia, in the first quarter of 1914 was valued at £441,180, which is £94,457 less than for the same period of 1913. Copper showed a reduction of £84,508, but molybdenite had an increase from £668 to £6628.



MILL OF THE AURORA CONSOLIDATED MINES COMPANY.

The New Aurora Mill

By An OCCASIONAL CONTRIBUTOR

The sale of the control of the Aurora Consolidated Mines Co. of Aurora, Nev., to the Goldfield Consolidated Mines Co., for almost $1,000,000, brings to light some interesting facts. It demonstrates that there is a demand for good mining properties with no lack of purchasers; that there is a chance for old camps to revive; that new methods in milling are making millions of tons of low-grade ore profitable, and that the distance from a railroad does not deter the building of an excellent mill and equipping the property throughout with the most efficient and up-to-date machinery.

Just before the sale of the control of the property by Jesse Knight to George Wingfield and Albert Bureh, representing the Goldfield Consolidated, there were in Salt Lake City four other interests actively bidding. It required $388,000 in cash to close the bargain, with notes from the Goldfield Consolidated endorsed by Mr. Wingfield for the remainder. Among those who made verbal or written offers for the property were Morton Webber; a Toronto engineer, representing Ellis P. Earle, president of the Nipissing; John W. Finch, representing the Amalgamated Copper interests; representatives from the United States Smelting, Refining & Mining Co., and O. J. Salisbury, of Salt Lake City, who is believed to have represented certain porphyry copper interests.

Early History

In the sixties, Aurora was one of the big mining camps of the West, as witnessed by the ruins of the buildings. It was in this camp that Mark Twain made his home, and so down at the heel was he at the time, it is said that he collected champagne bottles and scattered them about his back door to give his little cabin an air of prosperity. During the life of this camp it is reported to have had a production of $30,000,000 and no less than 13 mills were built at the various mines. When work was first started on the Aurora Consolidated in September, 1912, there was by actual count 14 people in the once flourishing town. Today Aurora has about 300 inhabitants, and there are nine places where liquid refreshments are poured.

The nearest railroad point to the camp is Thorn, Nev., on the Southern Pacific, from which there are two stages running to Aurora each day, covering the 32 miles in about two hours time. On account of the grade all the freighting into the camp is by way of Hudson, Nev., on the Nevada Copper Belt Line, which is a distance of 62 miles from Aurora.

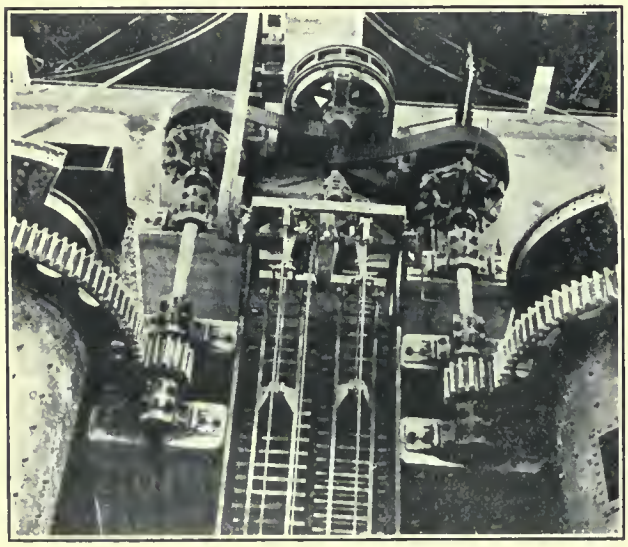
It was in 1912 that Charles E. Knox and John H. Miller secured an option on the Cain Consolidated Mining company property, which owned the principal mining claims in the camp of Aurora. They succeeded in interesting Jesse Knight and the Aurora Consolidated was organized. In September of that year work was started in a small way and continued until June 1913, when it was decided to build a 500-ton mill. W. Lester Mangum was made general manager. Morris P. Kirk and John H. Leavell of the firm of Kirk & Leavell, were given instructions to design the mill, and Mr. Leavell, with the title of manager, was placed in charge of the development of the property and the construction of the mill. Mr. Kirk became the consulting engineer. Ground was broken for the mill on June 20, 1913 and on June 15, 1914, the crushing of ore was started. Since then the amount handled has been gradually increased.

Although the number of mining claims brought into the Company by the Cain Consolidated was quite large, many more have been added. The management of the Aurora has during the past year purchased a number of others, until today there are some 52 claims held under patent or in the process of patenting. Embraced in this territory are some of the most famous claims of the camp, having between 30,000 and 40,000 ft. of underground workings.

The Aurora mine is opened by a long adit which is now being extended from the Humboldt shaft workings toward the Del Monte or Last Chance hill country, with branches to the Durand shaft and the Juniata mine; opening these workings at a depth of about 500 ft. The Last Chance hill was famous in the early sixties and eighties as a producer of high-grade ore. From local sources its production is estimated at over $20,000,000, the entire output having been won between the surface and the 200-ft. level, at which point the veins were lost. In some of the old pillars today in this part of the property are to be found pieces of gold ore that will carry from $4000 to $5000 per ton in gold.

Del Monte Shaft

At the Del Monte shaft there is an old Cornish pump, which at the time of installation, was the largest in the United States, and cost, laid down at Aurora, about $150,000. It was hauled by team from Stockton, California. The corner-stone of the building that housed this installation has carved upon it in large letters, 'Wild West Mining Company, 1862.' This block of stone weighing several tons is now used as a mantlepiece for the fire-place in the manager's cottage.



MOTOR DRIVING TWO TUBE-MILLS.

The ore is chiefly gold, with a small amount of silver, averaging close to $5 per ton and disseminated quite evenly through a hard quartz. The quartz veins vary from 30 to 80 ft. in thickness and run through an andesite formation. On account of the hardness of the rock scarcely any timber is necessary. The mine has been developed for mining by the shrinkage stope system, to which the property seems particularly adapted. It is estimated that the cost of mining will be $1 per ton or less. The mine is electric lighted and equipped with an electric haulage system.

The ore is drawn from the chutes into 20 car trains, drawn by a 4½-ton electric locomotive. The cars are double truck, side dump, and were especially designed for the work. From the mine the train travels over a short tram to the mill. The cars are automatically weighed, no stop being necessary. They then pass over the steel ore-bins where they are dumped for the coarse crushing plant. The trains then make a complete circle and come back to the main tracks.

From the coarse-ore bins, which are of steel, the ore passes through a 7½ Gates crusher. Thence it passes over a Gates screen, where everything over an inch and a half is sent on to two No. 5 Gates crushers, where it is reduced to 1½ in. Joining the undersize from the screen, it passes to the conveyor belt and is carried to the head of the mill, where it is further elevated by a Gates elevator, carrying it to the sampling plant. A 500-lb. sample is taken each day from the 500 tons going through the plant.

From the sampling plant the ore passes to another conveyor by which it is carried to four steel ore-bins having an aggregate capacity of 1600 tons. From this point the ore passes through feeders to the stamps, where it is crushed to pass a quarter inch. From the stamps the ore passes to Callow tanks and then to Dorr classifiers. Thence it goes to 6 by 16-ft. tube-mills and a second Dorr classifier, where the —200-mesh material is taken out. The + 200 goes to a second tube-mill where it is reground until all material passes 200 mesh.

From this point the ore goes to three Dorr thickeners where it is reduced to a consistency of one to one. From the thickeners it passes through a series of 5 Dorr agitators and from the agitators to 4 Trent replacement machines, where most of the gold in the cyanide solution is replaced with water. From the replacement machines the pulp goes to three Trent filters where a large portion of the remaining cyanide solution is taken out, the tailing going to waste.

From the Trent replacement machines and the Trent filters the gold cyanide solution flows by gravity to the lower end of the mill where it is pumped through Merrill clarifying presses, which are set on the thickener floor. From this point the gold solution flows by gravity through two Merrill precipitating presses, where the precipitate is separated from the solution and sent to the refinery, and the barren cyanide solution is pumped to the stock tanks at the head of the mill. There they are enriched before being started through the mill again.

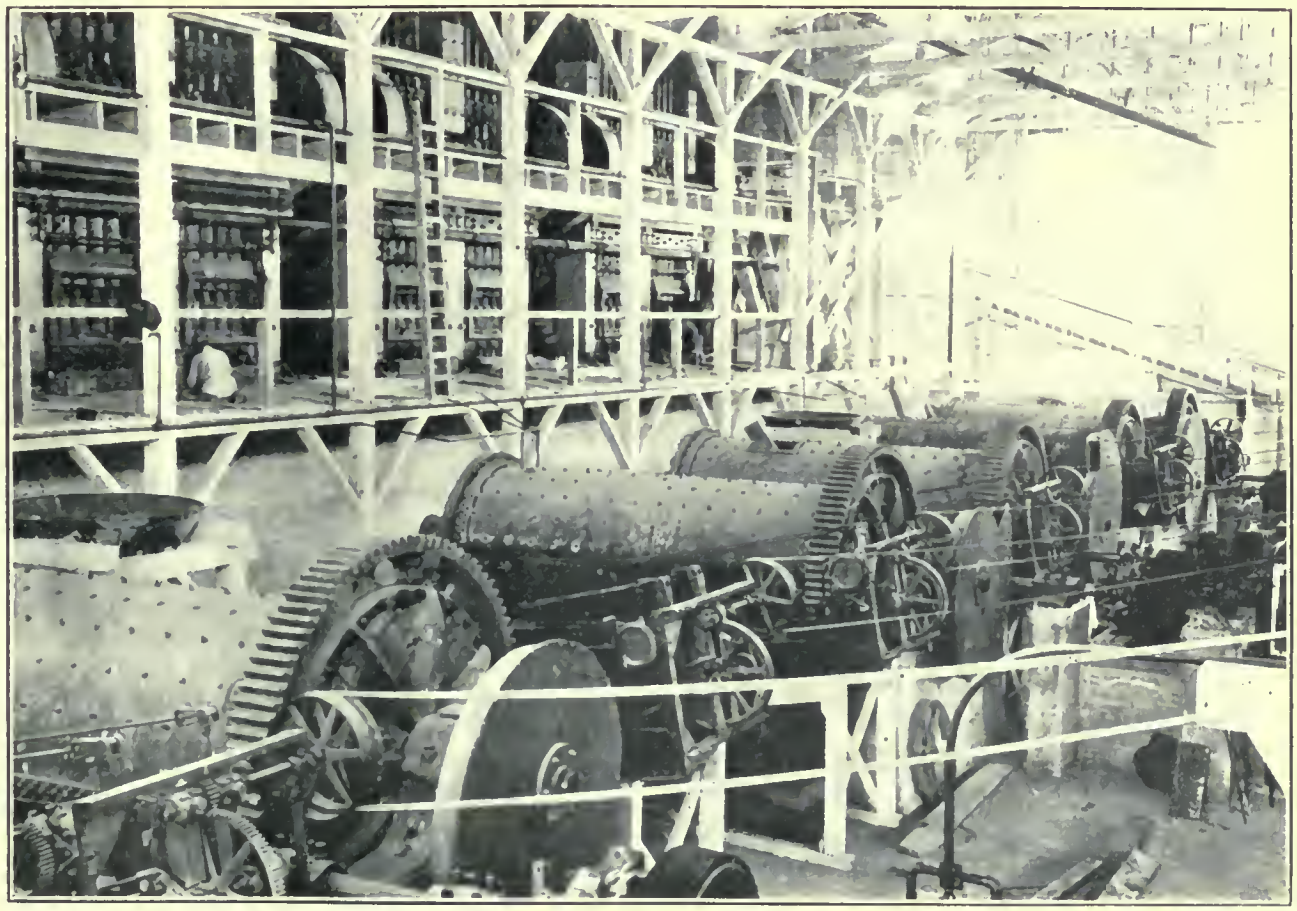
Heavy Stamps

Several unique features have been incorporated in the design of this mill. One of these is the heavy stamps that are used. These weigh 1660 lb. each, being among the heaviest in use in the United States today. Heavier stamps have been used with much success in gold mining practice in the Rand. The stamps are in batteries of five. Each battery is driven by an individual back geared motor of sufficient power to lift the stamps from rest and start them going without the necessity of hanging them up.

The 6 tube-mills, as previously stated, are 6 by 16 ft., which is a radical departure from the type of mills heretofore used in this class of work in that they are larger

in diameter and shorter in length. They are each capable of handling about 100 tons per day of stamp feed, crushing to 200 mesh. The tube-mills are arranged in units of two mills. Each unit is driven by a 150-hp. motor, with outboard bearings and Morse silent chain drives.

The 6 Dorr classifiers which feed these tube-mills are unique in the fact that they are the largest thus far constructed. The classifiers are driven by a 5-hp. motor driving a line shaft, which is the only one in the mill. The thickeners, agitators, and replacement machines are all individually motor driven. On the lower floor of the mill all the pumps are assembled in one room and are driven by individual motors.



INTERIOR OF THE AURORA MILL.

Another feature of the plant is the automatic incline electric elevator. On the opposite side of the mill from the conveyor is the elevator which runs up and down from the top of the mill to the bottom to facilitate the men traveling from one end of the mill to the other and also for the delivering of supplies to the different floors. The Trent replacement process which is in use at the mill has been tried out for over a year in Arizona in various plants and has met with considerable success.

Electric power is used throughout at the mine and the mill. This is furnished by the Pacific Power company, a subsidiary corporation of the Nevada California Power company. The power line is also connected with the main Nevada California power line so as to insure a constant flow of electricity. The current is delivered at the property at 60,000 volts and is transformed down to 440 volts for mill purposes.

The property is probably one of the best equipped in the country with machine-shop, blacksmith-shop, carpenter shop, assay office, warehouse, club house, main office, boarding houses and bunk houses for 150 men, superintendent's residence and cottages for various officials. The machine shop is equipped with a full outfit for repairing machinery of all kinds. It is said that there is hardly anything at the mill but what could be repaired in the shop. It has a 20-ft. lathe, planers, an oxy-acetylene welding outfit, and all kinds and grades of tools. The carpenter shop is equally as well equipped.

The mill has been well arranged for convenience and economy. It is declared that when running at full capacity only 18 men will be necessary to handle the full tonnage every 24 hours. This provides for a mill crew of four men working each eight hour shift, a repair crew of four men, a superintendent, and a metallurgist.

LEAD, SILVER, ZINC AND ORE SHIPMENTS from Broken Hill, New South Wales, in April were valued at $1,830,000.

MEN EMPLOYED at the Mt. Lyell properties, Tasmania, total 2100.

Simple Mine Accounts

Mine accounts are often more elaborate than a medium-sized mine warrants. Little mines often stagger under a ponderous system of red-tape which the chief clerk or cashier adopted from a big operator's system. In general, mines are not propitious places to quibble over bookkeeping technicalities. If the master mechanic wants a man-hole gasket and 'wants it quick,' he does not like to have to make out a lengthy requisition for it and charge it to the proper subdivision of the proper department; and if he is too much bothered by forms and clerical details, he will likely lose the company more money taking time to grumble over its inconsistencies than the extra red-tape will save.

In the Lake Superior iron ore district many of the medium-sized mines keep a fairly well-stocked warehouse and hire a supply clerk to tend it; frequently, he is also timekeeper, and he makes out the monthly payrolls, charges and delivers supplies promptly, perhaps keeps track of cars of ore shipped, and is a valuable unit in the force and picks up many details whereby he can save the company money.

Forms 2 and 3, the 'Oil Sheet' and 'Explosive Sheet,' are simple yet convenient methods for the supply clerk to keep track of supplies used in the different departments. At the end of the month he can total up quickly the amount of cylinder oil used in the engine house, the boiler house, pumps, etc., the amount of black oil used for underground cars, etc. Then, of course, the engine-house items are apportioned to shaft-sinking, driving, hoisting accounts, etc., according to how much of each relatively was done during the month. The oils and explosives are, by no means, the only classes of supplies which can be kept track of on a tabulated form. Whatever items are used in large amounts at any particular mine, such as perhaps timber or pipe-fittings, can be conveniently recorded on a sheet ruled by the clerk to suit his ideas of the matter. This is a more efficient method of keeping track of supplies than the complicated 'countersigned' order blanks sometimes afflicted upon a mine by its Eastern secretary or auditor. If the mine clerk is overwhelmed with red-tape so that he has little time for anything else, he cannot go out for an occasional walk around the plant and observe that a car of rails is being unloaded in the wrong place, or that the mine boss left the powder magazine door open and a cow has wandered in there.

The superintendent usually does considerable figuring, comparing, and planning over the monthly cost sheets. It is his guide and prompter; and it should be in his hands as soon as possible after the end of the month. At Lake Superior, the different accounts to which labor and supplies are apportioned and charged, include some twenty or thirty divisions of the mine work with items of exploration, development in rock, development in ore, pumping, stoping, hoisting, underground haulage, steam, air, and water lines, etc. It is also customary to tabulate on the cost sheet, a classi-

fication of the supplies used, so that the superintendent can see just how much timber, oils, and waste, explosives, candles, tools, rock-drill parts, pipe and pipe-fittings, rails and track supplies, etc., were consumed during the month. For conveniently arriving at the total cost of each classification of supplies used in each account of activity around the mine, a sheet having the general scheme of 'Form 1' is often used. This is a large sheet, ruled at the printer's, and perhaps several will be required at the end of each month, as all the records of supplies used during the month are transferred to it, including the contents of the 'Oil Sheet' and 'Explosive Sheet,' which can then be destroyed. This 'Form 1' is made out either by the supply clerk or the bookkeeper, and is then used in making up the cost sheet, as it furnishes a complete record of all supplies used and their costs.

For convenience in adding up the number of shifts which each man has worked, when payment is made monthly, time-books can be bought which have an extra column at the end of every week, in which the number of shifts for the preceding week can be marked, six (or five, perhaps) per man. Then at the end of the month, it is comparatively easy to add up the four weeks totals, rather than to have to count up twenty-five or so shifts one by one.

Kennedy Extension-Argonaut Decision

The following opinion was delivered by Judge Fred M. Wood, in the Superior Court of the State of California, in and for the county of Amador, in the case of the Kennedy Extension Gold Mining Co., plaintiff, *v.* Argonaut Mining Co., defendant, June 29:

The plaintiff in this case is the owner of the Muldoon quartz mine and millsite, a portion of the Jackson quartz mine, and a portion of the Jackson placer mine, embracing an area of 54 acres, contiguous territory. The defendant is the owner of the Pioneer quartz mine, adjoining plaintiff's property on the west, of the pioneer millsite and the Volunteer quartz mine, adjoining plaintiff's property on the north, and of the portion of the Jackson placer mine lying east of the Jackson quartz mine.

The plaintiff became the owner of its mining property in May 1909 and commenced operation of the property in the month of October following. Upon the Muldoon quartz mine there have been sunk two shafts, one of them to the depth of 1000 ft. with levels and crosscuts. Upon the Jackson quartz mine there has been sunk a shaft. No ore has ever been mined or milled by plaintiff, or its predecessors in interest, from any of its property mentioned. All the work that plaintiff has ever done, since its acquisition of the property, has been to clean out the old workings, and perform such other work as it deemed important to establish its claim in this action, and all of the property was idle for many years prior to plaintiff's ownership.

The defendant purchased its property in the year 1893, from the Pioneer Gold & Silver M. Co. Previous to the time of the acquisition of the property by defendant, a shaft had been sunk to a depth of some 70 ft. through the lava-cap lying over the apex of the Pioneer vein, and thence a drift extended northward a distance of 70 ft. along the vein. A tunnel was started in the Volunteer quartz mine, and driven 520 ft. to the Argonaut vein, and drifts driven north and south along the vein. Various other work of minor importance had also been done when, in 1893, the defendant started a shaft on the Pioneer millsite about 430 ft. down the slope and east of the apex of the Argonaut vein, and sunk it to the 1460-ft. level. This shaft was started on the millsite for the purpose of getting dump room, and to obtain sufficient pressure from the reservoir on the hill. Subsequently stations were cut, and levels opened, and stoping done from the 1200-ft. level upward to the 290-ft. level, where the shaft intersects the vein. In the regular and customary course of mining, the defendant extended its shaft, opening and developing various levels, and mining and milling the ore and minerals until, at the time of the trial, the shaft had been sunk to the 3900-ft. level on the incline. In developing the mine below the 1240-ft. level, and following what it claimed to be its vein or lode, the defendant company extended its levels, drifts, and openings, and extracted therefrom, and removed, ore and minerals of the value of many thousands of dollars, much of it underneath the placer lands owned by the plaintiff and its predecessors in interest. The damages caused by the removal of these ores and minerals are the subject of this litigation.

Claim of the Plaintiff

On the part of the plaintiff, it is claimed that the lode or vein from which these ores and minerals were taken formed no part of the so-called Argonaut vein or lode, and that it, plaintiff, is entitled to recover the value of all the ore and mineral mentioned, upon either one of two grounds: (1) its common-law right to the ownership of all minerals lying underneath the surface of its property, when not extracted from a vein having its apex within the exterior boundaries of land belonging to other persons; (2) that the ores were extracted from veins having their apices within the Muldoon quartz and Jackson quartz mines, extended downward within vertical planes of the end lines of such claims.

The defendant asserts, in its defense, that the ore-bodies mentioned were all obtained from, and formed a part of, the so-called Argonaut vein, having its apex within the surface boundaries of the Pioneer quartz mining claim.

As to the plaintiff's claim under the common-law right to ownership of the ores, the same may be elimin-

ated from discussion, for it can be sustained only by disregarding practically all the oral testimony of the witnesses, and the opinion of the experts. The real controversy in the action is waged over the location of the apex of the vein from which the minerals were extracted, that is: whether the ores were taken from veins having their apex within the surface of plaintiff's or of defendant's land, and the respective claims of plaintiff and defendant are based upon Section 2322 of the Revised Statutes of the United States.

Plaintiff's claim, under such apex right, to the ownership of the ores and minerals mentioned, is based upon what it terms the Jackson vein, by virtue of a union with the Muldoon gouge vein below the 950-ft. level of its mine. No continuous development of the vein has been made. It is not the discovery vein upon which the patent to the claim was issued, but developed exposures have been made upon which plaintiff has founded theory upon geological movements causing the formation of the great Mother Lode; that the Mother Lode fissure is a normal fault with a displacement of some 700 ft., and not an overthrust fault, as described by F. L. Ransome in the Mother Lode folio of the United States Geological Atlas: that instead of there being one vein with branches as claimed by defendant, and heretofore generally supposed to exist, there are a number of veins, formed at different periods of time, which by their faulting must have prevented any connection between the pioneer vein and the vein from which the ores and minerals in controversy were extracted.

It can serve no useful purpose to enter into a discussion of the testimony of many hundred pages given by experts in support and refutation of this theory. Upon the trial, the impression was strong in the mind of the Court that there was great probability of the correctness of this theory, and after a subsequent examination and consideration of the record, there is no attempt on its part to reconcile it with the positive and preponderating testimony of practical men engaged in mining, and familiar with the conditions in this mining district. Before this Court, however, will say that these men are all mistaken, and make a finding that will take the property in the possession of the Argonaut company, and award it to plaintiff, upon a speculative theory as to the convulsions and workings of nature countless ages before the time of man, it will require something more than a strong opinion as to the plausibility of a theory. As was said by the Supreme Court of Utah, in Grand Central Mining Co. *v.* Mammoth Mining Co., 83 Pac. Rep., at page 674:

> Science has not yet unfolded all of Nature's intricacies, and in all probability never will, to such an extent that the fallible human mind can fully grasp them, though indications may be revealed. To look at a mountain is one thing, but to look into the inner recesses of the earth, through surface indications is another. Every geologist, every miner, knows that, in determining the contents and actual conditions of a mountain by surface indications, even with extensive workings, which, after all, constitute but slight explorations compared with the whole mass, such difficulties are necessarily and invariably encountered as to produce differences of opinion, considering the same physical facts. Inductive reasoning has not attained such a high state of perfection as to lead all men, viewing the same parts, to the same conclusion as to the whole. This is especially true when the investigation of a portion of a thing is attended with great difficulty. In cases of stratified rock, where the beds are regular, it is comparatively easy to determine the location of a vein; its strike and dip; but where the beds are broken, tilted, and fractured, and in places fissures running in all directions, the investigation of one party may lead to very erroneous conclusions as to the formation and contents in general, or as to the location and course of a particular section or ledge, a small part of its location and course only being definitely known.

The mining laws of the United States are framed upon the ideas of the practical miner as to what constitutes a lode or vein, rather than those of the geologist. In this case, the testimony of practical miners, familiar with the conditions upon this part of the Mother Lode, is overwhelming that the Argonaut vein is continuous from the apex to the lowest level. Needless to state, all the expert witnesses for defendant concur in that testimony.

While the plaintiff in this case relies upon developed exposures only to substantiate its theory, and its claim to extralateral rights by virtue of its apex location, it contends that continuous development by defendant in its workings has disclosed interruptions or breaks in the so-called Argonaut vein which demonstrates that there is no continuity of the vein shown, as required by law. This, to my mind, seems to be the most serious objection to the adoption by the Court and qualified mining men of the inference of these experiences.

The Continuity of Veins

No arbitrary rule has been laid down which defines exactly what must be shown in order to establish the continuity of a vein. In speaking of this subject it was said by the Supreme Court of Montana, in Butte & Boston Mining Co. *v.* Societe Annonyme des Mines de Lexington, 75 A. State Rep., 513:

> "Laws of continuity," says Webster's Dictionary, "the principle that nothing passes from one state to another without passing through all the intermediate states." Speaking exactly by this definition, it would often be very difficult, if not impossible, for the challenged proprietor of a mineral vein to convince a jury of the continuity of a vein from one part to another, for there might not be continuity by actual contact of the parts of contiguity, which the precise word may literally mean must exist. Were such a rule inexorable, a failure of proof would not infreqnently be brought about by the inability of the miner to prove continuity without transition through intermediate states. The miner, therefore, might fall short of that exact measure of evidence required to establish a continuity of vein which excludes any interruption between one and another part of the identical thing, and, judged by too closely interpreted significations, the continuity of the vein would be lost. * * * Now, the miner's object is to disclose and mine the mineralized portion of the vein, and to do so economically. But he will not necessarily continue his exploitation from an initial point. He may work at numerous points on the vein, or he may drive a tunnel through extraneous rock to tap the vein at a point quite remote from his other workings.

It was said, by the Supreme Court of the United States, in Iron Silver Mining Co. *v.* Cheesman, 116 U. S. Rep., 529 (26 L. Ed., 713):

> Now, a vein containing the precious metals is by no means always a straight line contact of uniform dip or thickness, or richness of mineral matter throughout its course. Generally, the veins are found in what, when the mineral is taken out of them, constitute clefts or fissures in the surrounding rock, with a well defined wall above and below of different kinds of rock, as porphyry on one side, above or below, and limestone on the other. So long as these enclosing walls can be distinctly and continuously traced, and the mineral matter of the same character found between them, there can be no doubt that it is the same vein. But sometimes the cleft between the enclosing rock, called in mining parlance the country rock, diminishes so as to be scarcely perceptible. Sometimes for a short distance the fissure disappears entirely, and again is found distinctly to exist a little farther on. Again it is seen that, although the underlying and superposing country rock is there, the mineral deposit ceases to be found, but following the fissure it reappears again very soon. It also happens that both fissure and mineral come to an end and are found no more in that direction, or, if found, so far off or so deflected from the original line as to constitute no part of that vein. Of course, it is sometimes easy to see that it is the same vein all through. It is also easy to see in some instances the vein has run out; has ended. But there are other cases, of a class of which that before us is one, where it is a matter of extreme difficulty to lay down such rules for the guidance of a jury as will best aid them in arriving at a just verdict.

The Mother Lode Folio of the Geological Atlas of the United States at page 8, says:

> Thus there may be many small veins or stringers together constituting what has been called a stringer lead, or stringer lode. Most of the large mines of the Mother Lode are upon leads of this character, and their veins are really aggregates of many veinlets.

W. H. Wiley, a witness for defendant, testified at the trial:

> Veins, as I have seen them, are rarely distinct planes with two defined walls and one streak of quartz or other material between them, but they are usually complex, and in the case of the Mother Lode, there is no variation from this rule of complexity. They have been termed stringer veins. It is an apt designation in describing portions of these lodes.

J. W. Finch, an eminent geologist, a witness for plaintiff, in speaking of the Jackson vein, said:

> With its parallel stringers of quartz, there is a representation of a true stringer vein.

Other testimony in reference to stringer leads might be quoted, but that of these two gentlemen is selected because they were chosen by the respective parties to the action to accompany the Judge of this Court upon the view of the property, to point out for inspection the various places deemed important to be seen, to obtain a fair understanding of the testimony given to support the theory of each side. If a vein were always an ore-bearing filling of a single fissure, the difficulties encountered in this case and the wide divergence of experts' opinions would not exist. However, tested by the foregoing quotations, from the opinions of the Courts and of geologists, it does not seem that the inference drawn by the witnesses who are experienced in mining development in this district, is unwarranted by the evidence, when they say that the so-called Argonaut vein is continuous in its downward course through the placer lands of plaintiff, even though admittedly short interruptions in the vein are shown to exist.

In the presentation of its evidence to substantiate its claim by virtue of its apex rights, the burden was upon the plaintiff, Kennedy Extension Co., to show, by a preponderance of evidence, the apex and continuity of the Jackson vein, in order to overcome the evidence on the part of defendant in its attempt to show apex and continuity of the Pioneer vein; that it to say, that if the conditions were reversed, and plaintiff had been in possession, and mined the ore and minerals from a segment of the vein in dispute, under a claim that it constituted a part of the Jackson vein, less satisfactory evidence would be required to retain them than is now required to recover their value from the defendant, Argonaut company.

As before mentioned, there has been no continuous development to show the continuity of the Jackson vein. In support of its claim, plaintiff relies upon surface cuts, an exposure in the 180-ft. level of its mine, with drifts and upraises therefrom, an exposure in the 400, the 800, and the 950-ft. levels, with raises and cross-cuts on this last-mentioned level, below which it is claimed that there is a union with the Muldoon gouge vein, which connects it with a vein from which the ores and minerals in dispute were extracted. The patent for the Jackson quartz claim was applied for upon a discovery vein other than the so-called Jackson vein.

It devolved upon plaintiff, in its claim of extralateral rights upon this secondary vein, to show the existence of the vein to an extent necessary to cover that part of the vein in dispute, from which the minerals and ores in dispute were taken.

> Hayman *v.* Wheeler, 29 Fed. Red., 347.
> Argonaut Con. M. & M. Co., *v.* Turner, 48 Pac. Rep., 685.

Apex of Discovery Vein

Now, it is claimed that this apex comes to the surface and is not what is known as a blind apex. A series of cuts or trenches was made, which it is claimed show the course of this apex. Every witness for defendant, practical miners and experts, are positive that nothing is disclosed in these cuts which can be called a vein. As to the witnesses for plaintiff: Mr. Perry stated that a fissure was shown in each one; that there were numerous stringers of quartz east of the fissure, irregular and running in different directions. Mr. Devereaux, who had had more experience in mining upon the Mother Lode than any of the other witnesses for the plaintiff, in giving his testimony as a witness for plaintiff, said, that these stringers of quartz are a common occurrence in a slate country, whether near a large vein or not, and, as to some, he did not consider them a part of the Jackson vein. All the witnesses for plaintiff, however, are posi-

tive that the Jackson apex is sufficiently disclosed. The indications specified, with the other testimony, are sufficient, of course, to warrant an inference of the existence of the apex, but they also indicate that a different inference may be drawn. To me, however, it seems difficult to understand how this vein, with its apex at the surface, should remain undiscovered until the commencement of this action, after so many years of mining activity in this country.

There are vexatious and embarrassing questions involved in this case, some of which seem to be impossible of an entire and satisfactory solution by the human mind, looking at them from an impartial standpoint. Each side, apparently, can see no merit in the claim of the other, but, viewing the entire testimony of each side, weighed in the scales, it seems almost evenly balanced; but, as before indicated, this Court is largely influenced in its decision by the preponderance of the testimony of practical mining men familiar with its history, and its disinclination, upon the evidence produced, to take the property from the possession of the Argonaut company, which it has obtained by its discovery and labor in prosecuting the work upon what it had every reason to believe, and was generally supposed, to be the Argonaut vein. It was the intention of the Court to discuss in detail many of the interesting features of this case left untouched, but the opinion has been delayed through sickness and pressure of other labors, and undoubtedly both parties to the litigation will find more satisfaction in the announcement of a decision than in the perusal of a protracted opinion.

The Court is of the opinion and decides that the continuity and identity of the Argonaut vein is sufficiently shown to meet the requirements of the law; that the evidence does not satisfactorily establish the course of the apex of the Jackson vein: that the defendant, Argonaut Mining Co., is entitled to retain the proceeds of the ores and minerals extracted from the segment of the vein in dispute, and to a judgment for its costs. Let findings be prepared accordingly, and served and submitted in accordance with the statute.

Production and Uses of Tungsten

By O. J. STEINHART

Much erroneous information from time to time appears with regard to the metal tungsten and its minerals, so that some notes on the subject, especially with regard to the commercial value and uses of these minerals, may be of interest.

The most important of the tungsten minerals are wolframite, or wolfram as it is generally called, hübnerite, ferberite, scheelite, and wolfram ochre, or tungstite. Wolframite, hübnerite, and ferberite are essentially tungstate of iron, with varying percentages of manganese, and contain up to 76% of tungstic acid (WO_3). Scheelite is tungstate of lime, and contains as much as 80% WO_3 when pure.

As regards the occurrence of tungsten minerals and their main geological associates, it may be briefly stated that they generally occur in the older rocks of pre-Cambrian and Cambrian periods. Wolframite is also found in quartz veins in granite and also in pegmatite, often near and in contact with metamorphic schists.

Tungsten minerals are frequently found in conjunction with cassiterite. Their separation from the latter generally offers no serious difficulty by means of electromagnetic methods, but it is a difficult problem sometimes to separate very finely crystalline tin oxide and wolframite, especially in the presence of sulphides and arsenides. Such mixed concentrates have to be roasted, with the result that the cassiterite becomes coated with a fine layer of magnetic iron and is attracted by the magnet, so that further chemical treatment is necessary. In milling mixed tin-wolfram ores it is generally found that the losses of wolfram are greater than those of tin.

Many misstatements have been made as to the uses of tungsten. Writers have often copied notes in books on chemistry to the effect that wolfram is used to a considerable extent today in the textile industries and for the manufacture of certain bronzes. The total amount of wolfram consumed for this purpose would not exceed a few hundred tons. By far the most important application of tungsten metal and ferro-tungsten is the manufacture of self-hardening high-speed tool steel, which contains as much as 20% tungsten in conjunction with smaller proportions of other metals.

Another important application for tungsten is the metallic filament lamp. The consumption of metal, however, for this purpose is of subordinate importance, for one ton of wolframite should suffice to make 18,000,000 incandescent lamps.

It is also reported that tungsten is used in the manufacture of armor plate, but as facts referring to this subject are naturaly kept secret by the various governments, definite information is difficult to obtain. A further use, which, however, is not of great importance, is the employment of tungsten steel for the permanent magnets in telephones.

Prices are often based on 65% WO_3, and deduction of 2d. to 3d. per unit made for every unit below 65% down to 60% WO_3, below which figure a still greater deduction is demanded by buyers. It may be said that wolframite and its varieties form by far the greater portion of the world's supply, and scheelite is of secondary importance. Scheelite generally realizes from 1 to 3s. per unit less than wolframite.

Wolframite is easily identified by means of its streak, which is reddish brown, as compared with tin oxide, which is much harder and of a grayish white. If tungsten-bearing minerals are powdered and boiled for a few minutes with strong hydrochloric acid and metallic zinc added to this liquid, the yellow tungsten acid suspended and in solution will change its color to blue, owing to the formation of lower oxide of tungsten.—*Financial Times.*

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Tin Mining in Tasmania

The Editor:

Sir—In your issue of January 17 is a letter by M. G. F. Söhnlein, under the above heading, referring to an article by Mr. Tait of October 18 dealing, among other things, with the Anchor mine. As published in the yearly report, the figures are confusing.

There are two mines worked together, the Anchor and the Australian; the items (1) total ore treated, 104,732 tons; (2) black tin saved, 188.6 tons, includes both mines. The tin per ton, 3.42 lb., referred only to the Anchor mine. The correct figures are:

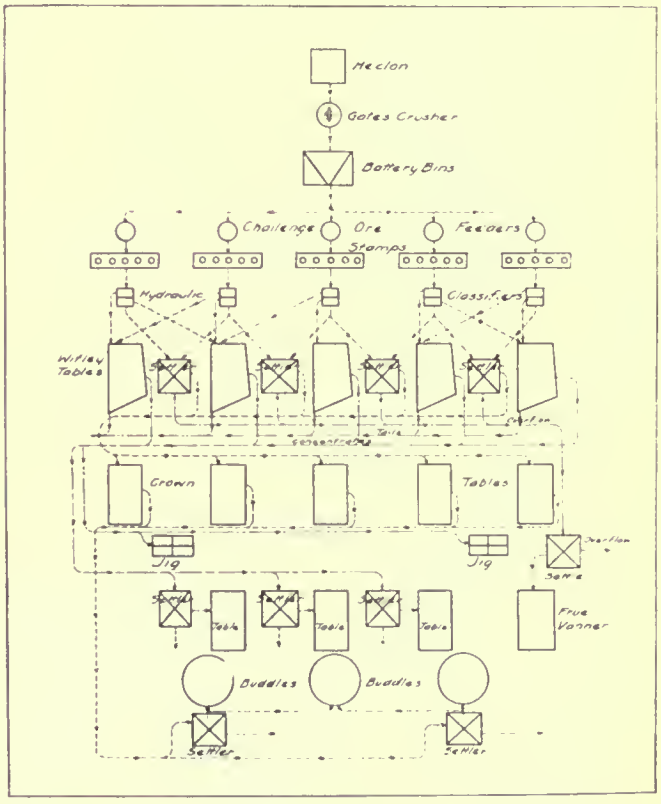
	Anchor.	Australian.
Stone crushed, tons	76,197	28,525
Black tin saved	134 t. 7 cwt.	63 t. 19 cwt.
Pounds per ton	3.42	5.02
Tons per stamp in 24 hours	5.38	6.11
Cost	3/6	3/6¼

These appear in another portion of the report. In all cases long tons of 2240 lb. are referred to.

His other assumption, however, that 50% is lost, is not borne out by experience. From our sampling, grab samples from the ore on the way to the battery, periodical sampling of pulp from the mortar boxes, individual sampling of tailing from different tables, and continuous automatic sampling of all the tailing, my conclusion is that the loss is not nearly so great. An examination and a sampling of the tailings deposited in the stream and on the flats below the battery, indicates a still smaller loss. As I am not satisfied with any of the results, however carefully they are worked out, I do not care to publish them. At the same time, it does not appear to me that the loss is greater at any time than 25%, that is, on Anchor ore—it would probably not exceed 1 lb. of oxide per ton of ore treated. On Australian mine ore, the proportion would be less.

It is only of late years that the Australian mine has been worked, and the average value of the ore for about ten years at the Anchor mine was 3.42 lb. oxide. The period referred to in the editor's footnote, in which a loss of $8500 was incurred, was for the financial year 1909-10. In some years a fair profit was made; for instance, in 1906-7, 153,738 tons was treated for a return of 2,206 lb. of metallic tin per ton, or 3.28 lb. black tin, at a cost of 55 cents; for that year 87.24% stamps crushed 5.85 tons per stamp in 24 hours, with a net profit of over £5000. With a constant water supply, a good run, and a decent price for tin, we can make a fair profit on ore with an average value of 3.42 lb. oxide. Unfortunately, for some years this has not been possible, and our yearly output has been reduced so that either the profit has been small or a loss has been made.

The stone worked is granite of varying degrees of hardness. Of late years it has been much harder, reducing the capacity of battery and increasing costs. As will be seen from the crushing returns (Anchor, 5.38 tons per stamp in 24 hours; Australian, 6.11 tons per stamp), the Australian stone is easier crushed and resembles the stone from the Anchor some years since. More or less overburden has to be removed, consisting of surface soil and barren granite. The latter is usually decomposed and capable of being hydraulicked, but contains hard masses and seams, in some cases forming 50% of the material. These have to be blasted and trammed to spoil banks. In some cases this overburden is over 70 ft. deep, and overlies only 30 or 40 ft. of profitable ore.



APPROXIMATE FLOW-SHEET, ANCHOR MINE, LOTTAH, TASMANIA.

The stone is run in some cases by gravity to the crusher station, but in most cases is hauled up inclined roads by friction winches. The crusher station consists of a No. 8 Heclon (Hadfield & Jacks); the

stone from this is elevated by a bucket elevator to a No. 4 Gates crusher, and from this goes to bins from which wagons are filled that run by gravity about 12 chains to the battery bins. Challenge feeders deliver the ore to 100 head of stamps in two sheds of 50 each. The stamps are nominally 1000 lb., but really about 900. From the boxes the pulp proceeds to simple two-compartment hydraulic classifiers. In the two sheds the arrangement of the concentrating plant is slightly different and immaterial alterations are continually being made. In the first instance, the products of classifiers went to two sets of double-compartment Harz jigs, but the ore was so poor that these were very imperfect concentrators. I would not care to use the jigs on a tin ore that did not contain at least ½% of fairly coarse tin. These jigs also required a considerable amount of power, and dressing water. In the present practice, the first and second classifier products go to shaking-tables (Wilfleys, Cards, or tables of our own design and construction). The overflow from classifier goes to settlers and thence to other tables. From the tables we get firsts and seconds, those from first floor go to jigs that remove any topaz or other heavy sand, pieces of iron, etc. They are then further cleaned by hand in a hydraulic dresser, and are bagged. These we can get up to 73 per cent.

The overflow from first settlers goes to other settlers that feed Frue vanners or shaking-tables. The tailing from tables on top floor goes to settlers that feed other shaking-tables, and from second floor to settlers that supply Borlase buddles on the bottom floor. These are very inefficient machines, but as they only require cleaning up about every six weeks, and only then produce a hundredweight or two of oxide, their presence or absence is not a serious matter. The concentrates from all these are re-dressed on the hydraulic dresser when coarse, and are dressed in a hand buddle and kieve or tossing tub when fine. The slime is first dressed on a Frue vanner and re-dressed in hand buddle and kieve. The tailing from all these is handled and re-dressed over and over again in the anciently approved Cornish method. The seconds we get up to 68 to 70%. This scheme is indicated approximately in the attached flow-sheet, which, however, omits many of the minor steps.

Many slime machines have been tried, including one of my own (which was a failure), canvas strakes, canvas belt tables, circular tables, etc., and we can find none better suited to our circumstances than the Frue vanner. It is not so efficient, however, as the shaking-table on the coarser tin, as it is of less capacity. The rubber belt also requires frequent renewal, and when the price of rubber is high we can make a complete shaking-table which will outlast many belts for less than the cost of one.

The ore is a good milling one, and fairly coarse crushing releases nearly all the tin. Tyler slotted screens with an aperture of 0.051 in. are used. More than half of the tin will pass through a 200-mesh screen. Power is from water, with two supplies, the main one of 380 ft. head, the smaller with 500 ft. head applied through a number of Peltons. For normal work, nearly 1000 cu. ft. per minute is required, and very rarely is available. The opening of the country for cattle grazing, and bush fires, has rendered the supply precarious, and the steep hillsides, broken into many narrow gullies, make water conservation on a sufficient scale impossible. Many schemes have been considered for improving the power supply, but financial difficulties have prevented their construction. The main water-race is about 30 miles long and contains several miles of timber flume which is always suffering damage from bush fires, floods, droughts, and falling timber. The earthen portion does not suffer so severely, its principal enemy being the 'platypus' (called for short the *Ornithorhynchus paradoxus*), which burrows into the banks and lets the water out.

The minimum rates for labor are $1.92 to $2.04 per 8-hour day. The local men usually are a fine class physically, use their brains, and are reliable. The casual hands are not so satisfactory. In the early days of the mine, rock-drills were used, but the result was not satisfactory. Lately hammer drills have been used with success for drilling the boulders.

It will be seen that there are facilities for cheap work, and that our costs could be reduced with a constant water supply. On the other hand, on the west coast of Tasmania, with a severe climate, and higher wages rate, there is the Renison Bell tin mine (which I am also responsible for), with a 10-head battery and an output of barely 20,000 tons per year, where the working costs at present do not exceed $1.44. This does not include prospecting and development costs, which at present are high, sometimes exceeding the amount spent in mining. The tin oxide here is much finer and more difficult to save than that at the Anchor and Australian mines. I am at present doubling the battery, and hope to reduce costs and increase output considerably.

I trust that I have supplied all the information desired by Mr. Söhnlein.

JAMES B. LEWIS.

Melbourne, Australia, April 21.

[The résumé of the milling practice at the Anchor property presented by M. Lewis will undoubtedly answer Mr. Söhnlein's query. We regret, however, that a more detailed analysis of production costs and milling results are not available. It is evident from the above letter that an extraction of much better than 50 per cent of the tin is being made, which with the confusing manner in which the Company's returns are published accounts for the apparent discrepancies. That low costs are common in tin mining is also evidenced by the returns from Mt. Bischoff, where the cost per ton of ore mined, which is mostly by open cuts, crushed, concentrated, and smelted at Launceston, 100 miles away, is only $1.15 per ton. With such a cost, comparatively low grade ore may be profitably handled.—EDITOR.]

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

BIRDS AND MICE are kept at the rescue stations of the U. S. Bureau of Mines in this country, and at rescue stations abroad, and form part of the rescue equipment at some mines. In testing for gas in mines small animals may be used repeatedly without danger of their being less susceptible to carbon-monoxide poisoning after many exposures than after the first, if they are allowed to recover between exposures, according to George A. Burrell, Frank M. Seibert, and I. W. Robertson. Canaries are less resistant to carbon-monoxide poisoning than mice, chickens, rabbits, guinea pigs, or dogs. It is recommended that canaries be used whenever possible and that at least three of them be carried by an exploration party. Men may display distress in the presence of proportions of carbon monoxide as small as 0.10%, whereas small animals in the same atmosphere may show no signs of being affected.

TEMPERATURES of air and rock in the St. John del Rey mine, Brazil, during the four hot months of 1913-14, namely, December, January, February, and March, are as follows, according to the annual report of the superintendent, George Chalmers:

Horizon number	Depth on incline, ft.	Air, Deg. F.	Rock, Deg. F.
Adit	300	77	78
8	2300	84	82
10	2800	85	85
11	3100	85	87
12	3400	86	88
13	3700	87	89
14	4000	89	92
15	4300	90	94
16	4600	91	97
17	4900	96	101
18	5226	97	101

All temperatures were taken in the downcast. A large Sirocco fan is in continuous operation, and another is being installed. When the workings are all connected with the main ventilating system, the following air temperature is expected: horizon 18, 92°; 17, 91°; 16, 90°; 15, 89°; 14, 88°; 13, 87°; 12, 86°; 11, 85°; 10, 84°; and 8, 82°. Rock temperature at the time of opening horizons is as follows: 8, 85°; 10, 89°; 11, 91°; 12, 94°; 13, 96°; 14, 99°; 15, 101°; 16, 103°; 17, 106°; and 18, 108°. The past year shows a slight reduction compared with the previous year.

FENDER CHAINS are being installed at the various locks at Panama to prevent vessels from possible injury to lock gates. There will be 24 chains in all, of which 15 have been made, and about four have arrived at the Canal Zone. They are the last of the large items of the lock operating and protective devices to be installed. The delivery of the chains, which are of unusual size, and present many difficulties in manufacture, has been uncertain. Chains have been under order at three different American chain works simultaneously, and the Panama canal is now inviting tenders from Europe for the remaining nine. The chains average from 418 to 434 ft. in length, and the two for protecting the lower guard gates at Miraflores locks are each 784 ft. long, being specially arranged on account of the tidal fluctuation. They weigh about 85 lb. per foot, nearly three times as much as the heaviest rails on the Panama railroad. The links are made from bars 3 in. diameter, and each link in the principal part of the chain is 17 in. long by 10¾ in. wide. The chains are designed to withstand normally a tension of 220,000 lb., or approximately 100 gross tons, which is about 50% of their breaking load.

GLACIERS in Alaska have been studied by the United States Geological Survey, and in a report on the coastal glaciers of Prince William sound and Kenai peninsula by U. S. Grant and D. F. Higgins the following is the

GLACIER ON THE ISKOOT RIVER, WRANGELL DISTRICT, ALASKA.

summary: Some of the glaciers described, the Valdez, Shoup, Columbia, those of Port Wells and the Bear, have been under observation on several occasions during a period of 10 years. On the whole, the glaciers here studied do not give uniform evidence as to a general retreat or a general advance within the last half century; some are evidently in a period of retreat and others in a period of advance, and the general balance between retreat and advance cannot be accurately determined by data now at hand. The accompanying halftone shows a glacier on the Iskoot river.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

Mining in Mexico.—Grenfell Failure and the Canadian Agency.—Dividends Passed by Mining Companies.—Chino Bonds.—Oil in Japan.—Butte & Superior New Claims.

The success of the Constitutionalist troops in Mexico is steadily putting one after another of the mining districts within the territory controlled by the rebels. Operations at Cananea and Moctezuma have not been seriously interfered with, and the American Smelting & Refining Co. is about to start its Chihuahua plant again. The Velardeña, Torreon, Matehuala, and Aguascalientes plants are now all in Constitutionalist territory, and as far as safety to the operating staff goes, could be blown in. But the first requisite for smelting operations is good transportation facilities, and, though the railroads are available, they are kept busy moving troops. It is reported that very little damage has been done to the smelting plants, and that the mines are in good order.

The Grenfell failure in London has many ramifications, one of which is the probable collapse of the Canadian Agency's mining operations in Nicaragua. This Company had taken an option on the Siempre Viva, which is controlled by New Orleans investors; the Bonanza, owned by Joe La Pierre; the Lone Star, owned by Richard McGinnis; and the Mars, a small property; all of them gold mines in eastern Nicaragua. Development work has been progressing in good shape, but in its present condition the Canadian Agency will probably have to let the options lapse, and the proposed consolidation of these properties will fall through.

At first thought it would seem that the present 'psychological' depression of business should have no effect on mining, but in one way or another it apparently has. Since January 1 the following mining companies have passed one or more dividends: American Zinc & Lead, Assets Realization, Copper Range, Dominion Steel Corporation, Mines Company of America, Mohawk, New Idria, Pennsylvania Steel, Quincy, and Tonopah Extension. The Calumet & Hecla reduced its distribution from $6 to $5; New York, Honduras & Rosario, from 3% to 2%; Old Dominion, from $1.25 to $1; Utah Consolidated, from $1 to 50c.; and the United Globe Mines, from $7 to $4. Some of these companies suffered from the strike in the Lake Superior region, and others from the trouble in Mexico; but the net result is that mining as well as general business is in a period of depression.

Out of the Chino bond issue, convertible into stock at $25, all but $3000 has been converted. The Bingham & Garfield Railroad bonds, exchangeable for Utah Copper stock at $50, have not been completely taken up, and $657,000 is still outstanding. The exchange privilege ceased on July 1.

Duluth investors have formed a new mining company, the Cactus Consolidated, organized under the laws of Delaware, with a capital of $1,000,000.

At the end of May, oil wells of the Nippon Oil Co., at Kurokawa, Akita prefecture, were gushing with considerable force. According to K. Ito, one of the Company's officials, work was started on one well early in April, and oil was struck at 1368 ft. The other five wells in the district, which required pumping, then started to flow to the surface. Until capped, the new well produced about 12,000 bbl. per 24 hours. Very little gas accompanies the oil.

On account of the Butte-Milwaukee Copper Co. selling its property to the Butte-New York Copper Co., the stock of the latter being controlled by the Butte & Superior Copper Co., the Butte & Superior secures five claims adjacent to its mine at Butte, and six claims in the Argenta district of southern Montana. The Butte-Milwaukee claims are a valuable addition to the Butte & Superior property.

About 65% of the gold output of Peru in 1912 came from copper ores treated at Cerro de Pasco, according to figures just published. This revival of one branch of mining stimulates others.

TORONTO, ONTARIO

Black Oil Struck 70 Miles from the White Oil of Calgary.—Canadian Goldfields Syndicate to be Liquidated.

Another find has been made in the Calgary oilfields, followed by a renewal in a somewhat milder form of the excitement resulting from the Dingman well. Crude black oil was found in the Monarch well on June 17 at a depth of 808 ft., and is believed to occur in quantity, but drilling was suspended until the well could be capped to avoid a rush of oil. The find is considered encouraging, as showing the extent of the field. The Monarch well is situated 30 miles west, and 6 miles south of the town of Olds, and is about 70 miles northwest of the Dingman well. There was a flurry of stock speculation when the announcement of the discovery reached Calgary, and the shares of the Company, of the par value of $1, sold as high as $50. The Monarch is capitalized at $200,000, and controls a territory of 122,952 acres. The second well on the Dingman claim, distant about 100 yards from the first, was at the last report down 250 ft. The first well will remain closed until ample storage facilities are obtained. The directors have ordered twelve 12,000-gal. tanks to be installed near the well. The pressure is sometimes as high as 360 lb. per sq. in., so that it is considered advisable to proceed with caution lest the flow of oil should become uncontrollable. The Calgary boom excites but a languid interest in Eastern Canada, and does not appeal to the speculative public to any extent. Heavy losses in Cobalt and Porcupine ventures and real estate at fictitious values, combined with the tightness of the money market, have rendered the lambs a good deal less frolicsome of late, and more disposed to heed the warnings of experts and newspapers against reckless speculation. Reports of other oil discoveries in the Calgary field and at other western points, have appeared, but have so far been unconfirmed.

At a meeting held in Montreal on June 18, the directors of the Canadian Goldfields Syndicate decided on a legal distribution of the assets of the Company, a meeting of the shareholders being called for June 28 to authorize liquidation proceedings. The plan proposed is that the properties in British Columbia be put up at auction in Montreal on August 4, and sold to the highest bidder. The Consolidated Mining & Smelting Co. stock held by the Company, together with any money received from the sale will be distributed among the shareholders *pro rata*. The Syndicate was organized at the height of the Rossland boom to trade in the shares of mining companies, but with the exception of the transaction which secured it 4270 shares of the Canadian Mining & Smelting Co. its ventures proved unprofitable.

WRANGELL, ALASKA

AREA AND HISTORY OF DISTRICT.—OPERATIONS IN THE THIBERT CREEK, DEASE CREEK, STIKINE, GLACIER, WOEWODSKI ISLAND, LAKE BAY, AND ISKOOT RIVER DISTRICTS.

The Wrangell mining district embraces a total area of 5130 sq. ml., of which 2200 is mainland and the rest islands. Kupreanof island is the largest, with an area of 1080 sq. miles. Fort Wrangell is the second oldest settlement in Alaska, having been established early in the nineteenth century by the Russian-American Fur Co. and subsequently was a trading post of the Hudson Bay Co. Gold was first discovered on the bars of the Stikine river in 1862, and the following year a Russian expedition was sent from Sitka into that district. In 1873, McCullough and Tibbitts, two prospectors, found their way across the Rockies, hunted for gold on the coast side of the range and started down the Stikine river. Natives directed them to Bock's bar, ten miles below Telegraph creek, where flour gold had been found. They reported the discovery of rich gold in what became known as the Cassiar country of northern British Columbia and Wrangell became the supply centre for the gold rush that ensued. An American garrison was established there. The Cassiar properties are the remnants of the richer placer deposits, and present activity is concerned with the low-grade deposits.

The Dease Creek syndicate has purchased the property of the Boulder Creek Mining Co. on Thibert creek, a tributary of Dease lake, and hydraulic operations are being conducted. Fifty men are operating four giants, the water being obtained from Boulder creek, where a 220-ft. head is available. The Company is owned by Lord Beauclerk and Warburton Pike.

W. M. Ogilvie, a son of former Governor Ogilvie of Yukon Territory who was the founder of the Yukon Gold Co., has been successful, it is said, in organizing a company in Montreal to operate a dredge in the Dease Creek flats. He prospected there last summer with an Empire prospecting drill and found a pay-streak at a depth of 40 ft. on the White Horse lease, which was purchased from J. Hyland. He returned recently and took the drill to McDames creek, where he now is prospecting. Bench ground in that district is looked upon as favorable for hydraulicking. Ten Chinese miners, who are remnants of a band of 50 which started work in the seventies, still work on the creek.——G. H. Pendleton, working on his claims 12 miles from the mouth of McDames creek, is finishing a bedrock drain two miles in length which he hopes will overcome the water trouble.——R. W. Mitchell and Finlay Mitchell are operating a hydraulic plant on Little Deloire creek, a tributary of Thibert creek. Pumps were taken in this summer and automatic gates and flumes are used to control the water. The Mitchell brothers have been working on the creek for 11 years.——The Dufflemeyer bench leases on Dease creek have been acquired by J. G. Galvin, a miner formerly of Nome, Alaska. Last winter two bedrock drains were installed, one 200 and the other 150 ft. long. Returning to Wrangell last month, he reported having found gravel assaying $6 per cubic yard. He brought out $400 in coarse gold obtained by panning. He intends to install hydraulic equipment before winter.——Captain C. Conover operates a lay on placer ground at the mouth of Clearwater creek on the Stikine river and is taking out a few thousand dollars each year.—— The Dease Creek properties are 400 miles inland from Wrangell. A journey of 160 miles by river steamer to Telegraph creek is necessary and from there a land journey of 72 miles and the rest of the distance by river boat from Dease lake.

L. Kirk, mining on the Stikine 25 miles below Telegraph creek, has two adits aggregating 500 ft. in length, which have been driven to open a deposit of bornite. Eighteen miles inland, J. F. Callbreath is prospecting a deposit of copper ore near Glenora.

The Johnson-Olson, Smith, and Nelson properties in Glacier and Ground Hog basins on the mainland 15 miles from Wrangell and eight miles from tidewater, have been optioned by W. D. Grant, United States deputy marshal at Wrangell. The three groups comprise 15 claims. On the Johnson-Olson property, adit work aggregates 150 ft.; on the Smith, 125 ft.; and on the Nelson 45 ft. The altitude of the properties is 3000 ft. A test shipment of 15 tons of ore has been made, part to the Treadwell mill and part to the Tacoma smelter. The average yield was $46.80 per ton. Engineers representing three companies will make an examination of the properties during the first week in July, according to present advices.

The Olympic Mining Co. claims on Woewodski island are being developed by E. E. Harvey. A 200-ft. adit and a 150-ft. winze comprise the present development. The Maid of Mexico property, three miles inland from the Olympic claims is also being developed.

Development continues on the Jackson No. 1 and Jackson No. 2 copper claims at Lake bay, which are owned by Allen McCullough, N. M. Tate, D. P. Gass, M. L. Burke, and L. Rinehart. A tram roadway has been built from tidewater to the claims, a tunnel has been driven 40 ft., and a 30-ft. winze sunk. Two other shafts aggregating 80 ft. make up the rest of the work. Four tons of ore shipped to the Tacoma smelter assayed 5% copper. One hundred tons of ore are on the dump, awaiting shipment.

ORE BUNKERS, JUMBO MINING CO., SULZER, ALASKA.

Burdell & Dickson have from 18 to 12 ft. of galena ore on their claims on the left limit of the Stikine 12 miles below the mouth of Clearwater. Samples assayed $200 to the ton. John Sales is developing a free gold property on Eagle Crag mountain, on the left limit of the Stikine, 45 miles from Wrangell. Berg & Son have a galena and a quartz property on Arens creek, 18 miles from Wrangell. A three-mile road has been built from the beach to their claims, preparatory to starting development work.

The Iskoot river is demanding the attention of the mining men of the district, although the inaccessibility of the region makes development costs prohibitive. The Iskoot is a tributary of the Stikine on the south side, entering about six miles above the international boundary line. A group of 14 claims seven miles below the cañon on the Iskoot is owned by P. C. McCormick, C. M. Coulter, Alex Vreatt, E. S. Busby, George H. Whitney, Bruno Greif, John Maloney, and F. E. Bronson. Nine of the claims will be crown granted (patented) this fall. A chalcopyrite deposit from 3 to 6 ft. wide has been traced with surface pits for a distance of 600 ft. Four adits have been driven, each 60 ft. long. Thirteen different veins have been developed since the claims were first staked in

1909. J. O'Sullivan, of Vancouver, B. C., has reported three assays of ore from the claims as follows: (1) 102.8 oz. silver, 18.4% copper; (2) 0.06 oz. gold, 41.0 oz. silver, 65% lead; and (3) 0.01 oz. gold, 6.75 oz. silver, 7% lead.

The rock exposures are slates, limestones, schists, and greenstones, highly metamorphosed. Chalcopyrite occurs in sheared zones of greenstone and also in quartz veins which cut the series diagonally. A report of the Tyee Copper Co. smelter at Ladysmith, B. C., shows the result of a test shipment of ore weighing 2324 lb.; copper, 10.45%; silver, 44.18 oz.; gold, 0.06 oz.; total value $44.11. The owners now are completing plans for another smelter test to be made before winter. The Iskoot is not navigable because of the rapidly changing current.

PLATTEVILLE, WISCONSIN

Dull Markets.—Spelter Stocks.—Prices.—District Production and Deliveries.—Buyers of Ore During the Month.

The month of June showed general depression in both metal and zinc ore markets. This, according to one of the leading smelter representatives operating in this field, is due to 75,000 tons of spelter remaining unsold, and now being carried on the inventories of the spelter manufacturers of this country. This representative added that no improvement in the metal markets need be anticipated for several months, if even then, but that as far as this field is concerned he looked for no greater curtailment in production than has already taken place. Production of raw concentrate declined considerably, and shipments include about 1000 tons of reserve ore carried over in bin for several months. The total reserve held in the field at the close of the month was a little over 5000 tons, the Wisconsin Zinc Co. reporting that it alone was holding 3000 tons of this amount. One of the leading buyers for the field reported the following average of prices for the month, including all grades produced in the Wisconsin field: 30%, $12.50; 35%, $16; 40%, $20; 45%, $24; 50%, $30; 55%, $34; and 60%, $38 to $40. Lead ore was out of favor all the period, metal ruling at $3.80 per cwt., with the best bid reported for ore at $45 per ton. Producers showed no inclination to respond and only three cars were shipped. Pyrite was off, and only one producer made any pretense to offer ore in quantity, shipments totaling less than one-half that usually sold. Carbonate of zinc ore ruled high, but producers were offered no market, and they contented themselves by cleaning-up their product and holding it in anticipation of a better demand.

Deliveries were made for the month by districts as shown in the following table:

Districts.	Zinc Pounds.	Lead Pounds.	Sulphur Pounds.
Galena	4,984,000	80,000	.....
Benton	4,216,000	.....	1,990,300
Hazel Green	2,410,000	60,000	.....
Cuba City	2,046,000	.....	.....
Livingston	1,920,000	.....	.....
Harker	986,000	73,610	.....
Platteville	924,000	.....	.....
Shullsburg	894,000	.....	.....
Linden	820,000	.....	.....
Dodgeville	342,000	.....	.....
Mineral Point	124,000	.....	.....
Highland	108,000	.....	.....
Montfort	78,000	.....	.....
Mineral Point Zinc Co.	2,988,400	.....	.....
Total	22,840,400	183,610	1,990,300

The gross production of concentrate for the month from all mines aggregated 17,710,320 lb. and net refined ore deliveries to smelter 11,234,730 lb. The Mineral Point Zinc Co., as usual, set the pace in bidding at all points in the field, and carried off the bulk of open market offerings. Heavier consignments of high-grade ore were made during the month and the field is prepared to make a better showing in this respect than ever before. The Dodgeville district, idle for several years, has come to life once more in the McKinlay mine, which is shipping regularly, and from which regular reports are now expected.

Sales were distributed among the buying concerns as follows: Mineral Point Zinc Co., 5094 tons; National Separating Co., Cuba, 1032 tons; Campbell Magnetic Ore Separating Works, Cuba, 640 tons; American Metal Co., 611 tons; Illinois Zinc Co., all premium ore, 558 tons; Empire Roasters, Platteville, 451 tons; American Zinc Co., Hillsboro, Illinois, 434 tons; Linden Zinc Co., 392 tons; Grasselli Chemical Co., 400 tons; M. & H. Zinc Co., La Salle, Illinois, 324 tons; and Joplin Separating Works, Galena, Illinois, 85 tons. The total was 268 cars, which is about 100 cars less than usually reported prior to April, 1913.

The northern half of the field appeared flat most of the month, as far as operations were concerned, while the opposite was true of all the districts in the southern half of the field.

YERINGTON, NEVADA

Bluestone Mine.—Pinegrove Development.—The Rockland Mine, Orebodies, Mills, and Proposed Treatment of the Ore.

It is locally reported that the Mason Valley Copper Co. has a bond on the Bluestone mine. Shipments are being made to the smelter at Thompson, and the sale of this property has aroused a great deal of interest in the district. It is one of the oldest mines in the copper belt, and considerably more than 1,000,000 tons of ore is said to be blocked out. The ore is a chalcopyrite, disseminated through altered limestone.

The Pinegrove Nevada Gold Mining Co. has been operating its 10-stamp mill all winter. Reopening of the old Wilson mine by this Company has stimulated prospecting in the district, and several discoveries of gold ore have been reported.

The Pittsburg-Dolores Mining Co. is operating the Rockland mine, three miles south of Pinegrove. This property was discovered in 1868 and has been operated at various periods since. The orebodies are in a fissure, formed by the intrusion of a wide rhyolite dike into granodiorite. Wherever the best orebodies are found today, the fissure is wide. The mine is opened by a series of adits and a depth of about 1000 ft. has been obtained. At the present time new chutes are being constructed, and some of the old drifts are being cleaned out to be ready for production by the time the new mill is completed. The first mill on the property was built about 1870 in Keene cañon, one mile north of the mine. It was destroyed by fire within a few months. After a number of years, during which time the high-grade ore found was hauled to the Wilson mill at Pinegrove, the property came into the hands of Gov. Blasdell of Nevada. He built a 10-stamp mill at the mine, and used the Washoe process in treating the tailing. Most of the development work in the mine was done during his ownership, and until the mill burned. After Blasdell's death the property was idle for some years. In 1902 it was acquired by the Nevada Chief Mining Co., which built a 5-stamp mill and concentrated the tailing from the plates. Later, a 15-ton cyanide plant was installed, but was not very successful, as it was found impossible to leach the tailing if it contained any slime.

The ore has always been difficult to treat. Ground to 100 mesh only about 20% of the precious metals can be caught on plates, and the best ore, which is a hard quartz containing pyrite, contains practically no free gold. Much of this was left in the mine and used as fill in the old stopes. In 1907 a dry-crushing mill of 75 ton daily capacity was erected, 14 by

27-in. Humphrey rolls being used for fine crushing. The product from these was leached in six 5 by 30-ft. leaching vats, but as the rolls would not grind finer than 10 mesh, an extraction of 50% was the best obtained. The present owners of the property are building a modern slime-treatment plant. All details of the proposed treatment are not available at the present time, but it is known that the product from the rolls is to be ground to 150 mesh in a tube-mill, and the slime agitated in the usual way. Extensive tests conducted by the management and by various testing plants have shown that an extraction of 95% can be obtained without serious difficulty. If such proves to be the case in actual practice, the mine should become a profitable venture.

GUADALAJARA, MEXICO

SITUATION IN TEPIC, AND ATTITUDE OF THE CONSTITUTIONALISTS. —EVERY MINE IN JALISCO SHUT DOWN.—MINING MEN KILLED.—CASADOS MINE LOOTED.

An American mining man of Tepic, Arthur F. Flynt, who recently arrived in San Francisco, states that mining operations are at a standstill in that territory. Mr. Flynt had just completed a 20-ton cyanide plant at the Purisima mine, a property that he had been developing for several years, and

HOSTOTIPAQUILLO DISTRICT OF JALISCO

had been milling at the Zopilote mine, another Tepic property that he had under lease from a German company. He remained in hiding at one of his mines following the American occupation of Vera Cruz, and up to a short time before the capture of the City of Tepic by the Constitutionalists, going into the Tepic capital after the rebels entered there. While in the capital he talked with General Obregon, the Constitutionalist commander, who told him that the friendship of his followers for the Americans would continue as long as no move toward intervention was made, and that the lives and property of Americans would be protected. If the Americans made any further advance into Mexico they would have the Constitutionalists to fight, the General said. Mr. Flynt reports that after Vera Cruz was taken, the Federal forces in Tepic confiscated all the property of the Grant Bros. Construction Co., the American concern that built the Southern Pacific railroad through Sonora, Sinaloa, and Tepic as far as the Tepic capital. Supplies of the Waters Pierce Oil Co. also were confiscated.

Letters received from the British and French consular representatives at Guadalajara state that all mines in the state of Jalisco, without a single exception, are shut down. The French consuls and vice-consuls, acting for the Brazilian minister at Mexico City, are now looking after American interests in Mexican territory still controlled by the Federals. It is understood that managers of Jalisco properties have no intention of resuming operations until peace has been restored, and guarantees for life and property again exist.

The only killing of foreign mining men as a result of the anti-American outbreak following the Vera Cruz occupation occurred at the El Favor camp in the Hostotipaquillo district of Jalisco, C. B. Hoadley, an American, and G. E. Williams, an Englishman, losing their lives. Hoadley was assistant mill superintendent at El Favor, and Williams was accountant. Both foreigners were stabbed to death, and later Hoadley's head and face were horribly mutilated to secure several gold-filled teeth from his mouth. Walter Neal, manager at El Favor, who was stabbed in the back, has entirely recovered from his injuries since reaching the United States, and now is acting as consulting engineer for the MaKeever interests, owners of El Favor, who also have properties in Montana and Arizona. The Casados silver-gold mine in the Hostotipaquillo district of Jalisco has been temporarily confiscated by Mexicans. The mine is the property of the Consolidated Mining Co. of New York and Los Angeles. It is stated that the Mexicans held the mine until the dynamite and other supplies found there were exhausted, and that high-grade ore to the value of ₱25,000 was taken out and disposed of to Mexican ore buyers. The Federal troops in the district either were powerless to drive off the looters or made no effort to do so.

BULAWAYO, RHODESIA

WORK OF THE RHODESIAN GEOLOGICAL SURVEY.—GEOLOGY OF GATOOMA DISTRICT.—CUSTOM MILLS SUGGESTED.—ASBESTOS AND CHROME IRON ORE DEPOSITS.—THE NEW MINES.

From an economic point of view, the report of the director of the Rhodesian Geological Survey for the year 1913 is certainly the most important that has yet been issued. This deals with operations for the third complete year since establishment of the department, during which period work was concentrated on the goldfields surrounding Gatooma in Mashonaland, which is the centre of what is probably the most extensive and valuable mineralized area in the territory.

About four or five miles from Gatooma is the Cam & Motor property, which is one of the three leading mines of Rhodesia. Close to the Cam & Motor are the Eileen Allanah and Eiffel Blue mines. The Gatooma district as a whole may be subdivided into other subsidiary areas, such as the Golden Valley and Shagari, each of which includes numbers of properties of some importance, the majority of them being worked by syndicates or tributing parties. In the Shagari district the gold-bearing belt consists of greenstones and felsites. Judging from the location of the successful mines, the greenstones appear to be the more favorable country rock, with the qualification that it is not the areas of pure greenstone, but areas of greenstone containing small bodies of felsite that are most productive. The larger bodies of felsite also contain numerous gold-quartz veins; but a number appear to be of small size, though rich in gold down to water-level. They have not been opened to any appreciable depth below this. Although large orebodies, requiring a considerable amount of capital for development and treatment will no doubt be discovered from time to time, the number of rich veins of the smaller size makes the district a favorite with the individual worker and small syndicate.

In his report, the director of the Survey, H. B. Maufe, makes a valuable suggestion in regard to the Shagari area, as fol-

lows: "The cost of a plant for treatment, and of its transport and erection, and frequently the lack of sufficient water at hand, are factors which retard the working of these veins. The Shagari district is one of those which should receive consideration in the event of a decision to erect custom mills, as recently suggested by the president of the British South Africa Co." Although the subject of custom mills is perhaps a little outside the province of a geological survey, this in no way detracts from the importance of Mr. Maufe's recommendation that the Shagari area should justify the erection of government-owned mills. Hitherto, custom mills, such as are provided by certain Australian governments, have been given but scanty attention by Rhodesian and South African authorities. A little money has been spent in this direction in Natal and Zululand, but generally speaking the South African governments have done practically nothing to directly help mining enterprises among the smaller capitalists. If the recommendation of the director of the Rhodesian survey is heeded, it may mark the commencement of a new epoch in mining in South Africa.

In other ways, the latest report of the Survey should be of considerable value to prospectors, as it contains a number of facts of interest relating to the distribution of gold veins in the Golden Valley and Shagari districts, and the character and mode of occurrence of different types of veins. Not much can as yet be said regarding the distribution of the gold within the veins themselves, as little really valuable information is as yet available. In the report, Mr. Zeally contributes some valuable observations on ancient workings in granite country east of Gatooma. It is of particular interest to notice that a conclusion announced in the previous year's report, namely, the close association of the gold ores with felsite, finds many examples in the areas considered in the present document, and is strikingly illustrated in the case of the Golden Valley district.

Discoveries of extensive deposits of asbestos and chrome iron ore in the Victoria district of Mashonaland are attracting a great deal of attention at present, both in Rhodesia and Johannesburg. A company with a capital of £125,000 has been formed to acquire and work the occurrences. A. H. Ackermann, Clement Dixon, Colin Campbell, and other mining engineers have reported favorably on the properties. The asbestos venture is known as the King's Asbestos, and in the course of his report Mr. Ackermann, the resident mining engineer of the British South Africa Co., stated: "I am much impressed with the possibilities of this asbestos property, and although little work has been undertaken to prove the extent of the area, indications at present are certainly most encouraging, and lead me to venture the opinion that it will be the means of opening a new and extensive industry in Rhodesia." The most favorable features in connection with this property are the high quality of the asbestos in the rocks as so far proved, the finding of profitable asbestos in every working place in the area referred to and outside, the facilities for a cheap system of bench mining, the proximity of a continuous supply of water and cheap labor, and the past satisfactory results of the owner's operation, which were undertaken under most adverse conditions. Of the chrome iron deposits, Mr. Ackermann says that it is not possible to gauge the extent of the deposits on account of no development having so far been undertaken. He suggests that immediate steps should be taken for the opening of these deposits, and said: "A few months' serious development work on these deposits should open up sufficient profitable chrome to justify the extension of the railway from Victoria to the bottom of the hill." It is understood that the discoverer of these deposits is Mr. Turner, who is well known on the Rand. Chrome ore production of Rhodesia in 1913 was 56,794 tons. Reports of a discovery of tantalite in the Victoria district are also current, and it may be that this area, which has so far been considered to be of agricultural value only, will yet develop into an important mineral-producing region.

The large new producing gold mines, such as the Shamva and Cam & Motor, have already had a favorable influence, and the gold output of 64,894 oz. in March easily beat all previous records. From now on a steadily increasing monthly return may be anticipated. The Shamva is understood to have made a profit of about £11,000 in April, and the Cam & Motor, despite treatment troubles, is reported to be doing well, treating 11,120 tons in May for gold worth $65,000. The Bell is also said to be securing good results. As these mines get into full working order, better yields will be forthcoming. The Antelope's production so far has been disappointing. The Falcon is expected to commence crushing within the next three or four months. As to the other mines, it may be noted that sinking the new vertical shaft has been temporarily suspended at the Globe & Phoenix, to allow of the erection of a new head-frame and hoist plant. The Eldorado Banket mine is reported to have opened some rich shoots of ore recently. This property's output in May was $44,000 from 4954 tons, with a profit of $20,000.

JOHANNESBURG, TRANSVAAL

MINERAL OUTPUT OF SOUTH AFRICA.—TRANSVAAL IN APRIL.—EAST RAND PROPRIETARY PROPERTY.—LITIGATION.

Exclusive of diamonds, the total value of the mineral output of the Union of South Africa for April was £3,193,255. Gold mining in the Transvaal, although slowly improving, has not fully emerged from under the cloud of uncertainty caused by labor troubles, the output of gold in April only totaling 687,988 oz. valued at £2,922,388, compared with 792,082 oz. valued at £3,364,550 in May, twelve months ago before labor troubles started. In April, the Transvaal had 92 producing mines with 9803 stamps and 293 tube-mills at work, yielding 687,816 fine ounces of gold. Considerable attention is at present devoted locally to the figures of the gold output of the Rand on account of the fact that since the labor troubles of July, they have until the last two months consistently shown a decline, in place of a steady increase as before. This decline has in many quarters created the impression that the Rand has reached its zenith as a gold producer, and the previous confident tone has given way to pessimism, so much so, that even the Chamber of Mines seems to have been affected thereby, as shown in the recent statement submitted to the Economic Commission. As far as possible, the Mines Department has attempted to minimize the bad effects produced by this statement; but the fact remains that some time must elapse even if the gold output of the Rand again assumes the steady progressive increase so characteristic of the industry prior to last July.

The last quarterly report of the East Rand Proprietary Mines shows that the shrinkage of profits indicated at the recent annual meeting has already begun and that the amount of development accomplished is still on the wrong side. The Company has now about £250,000 standing to the credit of the development suspense account, a good deal of which will have to be spent before the ore reserves of the concern are placed in a satisfactory position. The difficulty still continues of finding sufficient faces where the expenditure on development seems to be justified, a difficulty likely to be experienced until the area beyond the water dike is drained. When it is stated that a large quantity of water, estimated to flow at least at the rate of 3,000,000 gal. per day, has to be overcome, much of which has to be pumped from a depth of 4000 ft., the difficulties of the position will be easily recognized. Taken on the whole, therefore, it seems probable that at the East Rand Proprietary the position will probably grow much worse before an improvement can be expected, so that the outlook is anything but encouraging.

An interesting case between the Langlaagte Consolidated mines and the Victoria Falls & Transvaal Power Co., Ltd., has just been concluded in the Supreme Court. The former claimed damages from the latter, through the latter failing to supply the requisitioned power at the time agreed on, and was awarded damages to the extent of £29,000. At one time it seemed likely that several similar cases would be heard, but most of the groups affected compromised with the power company. Another interesting law case was that in which F. Gauf claimed compensation from the Apex mines for pointing out the outcrop of the Main Reef series lying on the Rietfontein property, between Boksburg and Benoni. This claim was made under a 20-year-old agreement, but it transpired from the evidence how little was known of the character of the Main Reef series so long ago. The judgment was to the effect that a few floating boulders of conglomerate had been taken by Mr. Gauf for the indication of the outcrop of the Main Reef, and he therefore lost his claim for compensation to the amount of £30,000. An interesting question arose during the trial as to what really constituted an outcrop, no less than six expert mining engineers and consulting geologists failing to satisfy the judge in this respect. The trouble arose owing to the conglomerate bed occurring as a sub-outcrop, and it was left for the judge to define an outcrop as 'the place at which a bed actually outcropped at the surface.'

MELBOURNE, AUSTRALIA

QUEENSLAND MINERAL INDEX.—MOLYBDENITE.—INSTITUTE OF MINING ENGINEERS.—ELECTRICAL WORK IN AUSTRALIA.

The Queensland Government has issued a 'Queensland Mineral Index and Guide,' which constitutes the first attempt made by the mines department in any of the states to advertise the mineral resources of that state. It cannot be said that the production is quite up to the best standard of Canadian and American work in the same line, but it is not so very far behind, and in accuracy and thoroughness it leaves nothing whatever to be desired. Australia has always been too anxious to keep her good things to herself to do very much advertising; but this publication is only one of many signs that a more liberal policy is being entered upon. There is, however, much to be said for the hint suggested by the *Australian Mining Standard*, that it is not very much use advertising the mineral resources of any state till the laws have been sufficiently liberalized to offer some inducement to foreign capitalists to put their money into local mining properties. Without something like real security of tenure they are not likely to take the risk of any great investment of capital.

It is amusing to note how suddenly molybdenite has become prevalent throughout the whole of Australia. Queensland has mines which it claims to be the best in Australia; New South Wales makes similar claims, with perhaps less warrant; Victoria is working some deposits on which the government geologist has just reported; Western Australia and South Australia both report discoveries which, as a matter of course, are expected to prove valuable; and it is understood that Tasmania also has its discovery of the mineral. There is no need to point out to readers of the *Press* that all these discoveries are closely connected with the extraordinary increase in the market value of the metal. It is not unnatural that when the metal is wanted it should be looked for; but it is surprising to learn of so wide a distribution of so supposedly rare a mineral. In some cases of course, the presence of the mineral was known previously, and the market rise has led to the exploitation of deposits hitherto neglected; but it would not be very surprising to learn that one or two of the discoveries are not quite so 'molybdenous' (if such a word may be coined) as is represented.

The annual meeting of the Australian Institute of Mining Engineers was this year held in Melbourne and was a poor affair, attracting a much less representative gathering of the leaders of the profession than it has done hitherto. The arrangements were by no means satisfactory, and the program was uninteresting. Victoria is a state that does not offer much of interest to up-to-date mining men; but certainly a poor selection was made of what it had to offer. Bendigo is unquestionably the most interesting field in the state, the most extensive in its operations, and the greatest centre of mining industry. Yet Bendigo was not visited, nor was Ballarat, Daylesford, or Ararat. Instead of these, a visit was paid to Walhalla, once famous owing to the yields of the Long Tunnel and Long Tunnel Extended, but now worked out. The only other place honored by a call was Wonthaggi; the scene of the government's experiment in

PART OF THE STATE OF VICTORIA.

coal mining, an experiment for which a strong effort is being made to have it regarded as a success, but which would in point of fact be regarded as a failure if it were being worked by a public company instead of by the state. [The mine produces about 2000 tons of coal per day.—EDITOR.] Altogether it cannot be said that the Australasian Institute of Mining Engineers is on the up-grade.

A leading article in the *Australian Mining Standard* on 'Electric Work in Australia' has attracted considerable attention, and, strangely, but significantly enough, has been generally endorsed by some of the large electrical firms. The article begins with a statement that "the work of the Victorian and Australian cities requires to be put upon an entirely new basis," and proceeds to ask, "why incompetent workmen should ever have obtained a footing there. Men are not permitted to touch gas pipes or water pipes without possessing a license. Why, then, should absolutely unlicensed men be allowed to meddle with the important work of effecting electrical installations in either dwelling houses or business houses? It is believed, and the belief is probably not very far from the truth, that there are more incompetent men engaged on this work than in any other part of the building trade; and the amazing thing is that the insurance companies have not before this taken a hand in the matter, and insisted on the electrical work being done to their satisfaction before they will consent to insure properties in which the electricity has been installed."

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ARIZONA

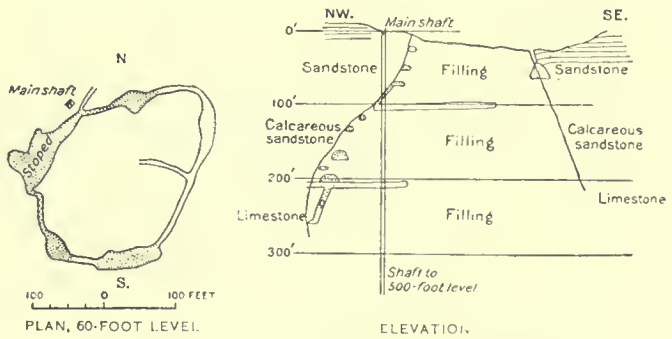
Gold, silver, copper, lead, and zinc were mined in Arizona in 1913 to the value of $70,875,027, according to Victor C. Heikes of the U. S. Geological Survey, showing an increase, as compared with 1912, of $3,824,243. The value of the gold production in 1913 was $4,023,911; silver, $2,384,647; copper, $63,228,127; lead, $710,370, and zinc, $527,972. There were 438 mines producing these metals in the state in 1913, as against 445 in 1912, and the total quantity of ore sold and treated was 7,931,862 short tons, an increase of 1,091,780 tons.

Cochise County

Sulphide ore has been opened in limestone in the Calumet & Arizona company's Cole area at Bisbee.——The Copper Queen test mill for the low-grade ores of the Sacramento hill and Czar shaft upper levels is nearly completed. Churn-drilling is still under way in this area.——The Shattuck mine is developing well, and ore shipments amount to 400 tons per day.——The Mascot Copper Co., operating at Dos Cabezas, is to construct a line from the South Pacific near Willcox and connect with the Maricopa Copper Co.'s line at Dos Cabezas, a distance of 18 miles. A company called the Mascot & Western Railroad Co. has been incorporated with a capital of 5000 shares at $100 each.

Mohave County

The Grand Gulch mining district is described by James M. Hill in *Bulletin* 580-D of the U. S. Geological Survey. He examined the mines there in November 1913. The district is most easily reached from Moapa, Nevada, on the main line of the San Pedro, Los Angeles & Salt Lake railroad, and 28 miles northwest of St. Thomas, Nevada, the supply point for



PLAN AND ELEVATION OF THE GRAND GULCH MINE.

part of southeastern Nevada and northern Arizona. The climate is typical desert weather, and there is a fair quantity of timber available. The Grand Gulch mine is 54 miles east of St. Thomas. It has been developed by a shaft 500 ft. deep, and levels have been driven at 100, 200, 300, and 400 ft. Owing to the peculiar shape of the orebody the levels are generally of circular plan. At 200 ft. the ore zone is about 300 ft. diameter. In the upper portion of the mine the ore is in sandstone, in the lower portion in limestone. The ore consists largely of malachite, azurite, and brochantite, with irregular masses of chalcocite scattered through it. The ore does not extend below a depth of about 250 ft., there being no copper minerals at 300 or 400 ft. The copper was deposited in the upper workings by generally downward-moving waters. Fifty men were employed in the fall of 1913. The Bronze L. mine is 3 miles southwest of the Grand Gulch, and has been opened by a 200-ft. incline shaft, now caved to about 100 ft. The ore minerals are largely sulphides, with smaller amounts of azurite and malachite. The Copper King mine is 40 miles east of the Grand Gulch mine, near the Colorado river. Every two months a carload of 23 to 26% copper and $3 to $4 silver ore is shipped by Bishop Whitehead.

Yavapai County

(Special Correspondence.)—There is a revival of mining in the Thumb Butte district, and miners are busy at many claims.——The Little Jessie mine, at Chaparal, is producing ore again, and gold ore is being sent to the Hayden smelter.

CALIFORNIA

Amadoa County

A retaining dam is being erected by the Kennedy company to store the tailing delivered on Bright ranch by the wheels described in this journal of May 9, 1914.——The Bunker Hill company has declared its monthly dividend of $5000, making $30,000 for the current year, and $732,000 to date.——More miners are being employed at the Plymouth, preparing the mine for supplying ore to the new mill, which is well under way.

Eldorado County

A 12-drill 2-stage air-compressor and other equipment has been installed at the Oro Fino mines, Shingle Springs, controlled by the Tredwood Syndicate, Limited, of London. Development of the lower levels is now under way. C. H. James is resident manager.——Seven mines, in the Volcanoville district, near Georgetown, known as the Ruby Consolidated Mines, and including the Aphrodite, Pluto, Proserpine Wedge, Garfield, Garfield Extension, and Little Gem have been bonded to a corporation headed by W. I. Smith from W. C. Green.——The fiftieth anniversary of the Bullion Bend hold-up, in which the Washoe stage was robbed of gold worth $60,000, was observed at Placerville on July 2. The men were captured and several killed, but the metal was never recovered.

Mariposa County

(Special Correspondence.)—John McAllester and associates have taken a working bond on the Sweetwater group of claims, which has a 10-stamp mill and other equipment.——Herman Schlagerter of San Francisco has been visiting his brother Charles A. Schlagerter at Mariposa, and has examined the Hite mine on the south fork of the Merced river, which is idle for want of capital to put the necessary equipment on the property.——There has been nobody from the State Mining Bureau in this field since 1896, until F. L. Lowell came here recently. He has some difficulty in properly finding unpatented claims of recent location. It is suggested that county supervisors could pay the salary of a Bureau officer, and have the mining areas thoroughly examined, as the appropriation of the Bureau is limited for this work.——Judge J. J. Trabocco of Mariposa, in the case of Sidney *v.* Pierce on injunction proceedings has increased Sidney's bonds from $1000 to $4500. This case involves the title of the Buena Vista copper mines in the Green Mountain district, in which Sidney claims the property by prior location, and has sued Pierce to recover the property. Pierce located the property July 9, 1912, and has been developing it, and mined and shipped $35,000 worth of copper ore.——The Sunnyside mine at Sherlock, owned by Mrs. Emma

Klopp of Oakland, is a promising property, and a good deal of prospecting has been done. Besides the mine equipment, there is a mill with rock-crusher, two 1000-lb. stamps, Hendy triple-discharge mortar, Chilean mill, plates, and a concentrator. The output in 1913 was 300 tons of $20 ore.——The No. 5 mine near Hornitos has been sampled by T. C. Parker, and machinery may be erected by the Merced owners.——The Monte Cristo claims have been examined by A. M. Rockwell of Los Angeles.——Homesteaders locating on mineral land which is of no value for agricultural purposes, in this county is quite a scandal here and should be stopped. The Virginia mine is being troubled by men who have filed a homestead on the ground from which the mine secures its water.

Mariposa, June 24.

PLUMAS COUNTY

Rich ore has been opened in the Arcade mine near Greenville by the owner, D. McIntyre.——Diving suits are being used by W. Wright and A. B. Knapp to prospect gravel in the north fork of the Feather river, near Belden. They are working for about 30 minutes at a time in 10 to 15 ft. of water.——Sluicing and other work is in full swing on Nelson creek, and there will be plenty of water for another month.

SHASTA COUNTY

The Mountain Copper Co. has arranged to install at Keswick, 50-hp., 60-hp., 75-hp., and 100-hp. induction motors which have been purchased from the General Electric Company.

SISKIYOU COUNTY

Owners of the Great Northern mine, an old producer, are mining ore for a test run. If satisfactory, the old McCook mill will be moved to the property.

TRINITY COUNTY

(Special Correspondence.)—Everybody has had a good season's hydraulicking. Lorenz Bros. have just finished a satisfactory run on the old Junkan's ranch, or lower Weaver Creek mine.

Weaverville, June 30.

TUOLUMNE COUNTY

(Special Correspondence.)—The collar of the App mine shaft is being repaired, and other work is going on with a view to resuming mining. It is understood that a portion of the mill will be put in working order at once for milling the ore on surface.——The Burnham mine, on Knights creek, recently bonded to M. Johnson, is yielding high-grade ore. A 480-ft. adit is being driven, through which two veins will be worked.——Sinking and driving is in progress at the Franco Contention mine, in the Jupiter district with 30 men. The prospects are most encouraging, and additional machinery, including a large hoist, will be installed in the near future.——At the Ditch mine, the 1650 and 1800-ft. drifts are being extended toward the rich shoot that made a record for the property nearer surface a few years ago. The mill is operating continuously with good results.——The Leap Year gravel mine, near Jamestown, has been bonded to George Tatton by Joseph Hoskins, and an effort will be made to open the auriferous deposits, which are believed to be but a short distance from the point reached by the former operators.——Thirty-five stamps of the milling plant of the Shawmut mine are in operation. The ore is conveyed from the hoist in the mine to the mill in electrically operated cars, an improvement which was only recently finished. A portion of the force employed is still engaged in making repairs and improvements that will add greatly to the efficiency of the plant.——It is reported that negotiations are under way for the consolidation of the Mack and Longfellow mines under new management.——The Mt. Zion mine, in the Groveland district, is being reopened by Ernest Caplinger. The shaft has been cleaned and repaired to the water level and some development work will be started in the upper workings soon.——The Company operating the River Gravel mine at Jacksonville has men engaged in cutting a trench to divert the waters of the stream, and at the earliest possible time a restraining dam will be under way. The Company expects to wash a large quantity of gravel this summer.

Sonora, July 3.

COLORADO

LA PLATA COUNTY

The new Cave Basin district is 435 miles from Denver, of which 425 miles is over the D. & R. G. line to Ignacio, then 10 miles by stage to Bayfield. The district is over 9000 ft. above sea-level. The ore, which occurs in limestone, contains gold, silver, and copper. Some high-grade ore was shipped to Durango last September. A fair amount of prospecting is now being done on the various claims.

TELLER COUNTY (CRIPPLE CREEK)

Estimates of the June output of the district, made on July 1, give the following totals:

Plants.	Tonnage.	Av. val.	Gross val.
Golden Cycle	31,000	$20.00	$ 620,000
Portland, Colorado City	9,500	20.00	190,000
Portland, Cripple Creek	18,800	2.40	45,120
Smelters	4,060	55.00	223,300
Stratton's Independence	11,823	2.50	29,557
Colburn-Ajax	4,140	7.00	28,980
Wild Horse	1,200	3.24	3,888
Neville-Free Coinage	600	6.00	3,600
Gaylord-Dante	1,500	2.30	3,450
Kavanaugh-Jo Dandy	1,850	1.40	2,590
Isabella mines	750	2.00	1,500
Total	85,323		$1,151,985

The Vindicator company and lessees shipped about 3500 tons, worth $165,000. The United Gold Mines, worked under lease, produced 400 tons of ore. From the Abe Lincoln 450 tons of $21 ore was mined. Lessees at the Dexter extracted 665 tons, worth $12,000.——The Golden Cycle was the only company to pay a dividend in June, the amount being $45,000. ——July dividends are estimated at $250,000.

IDAHO

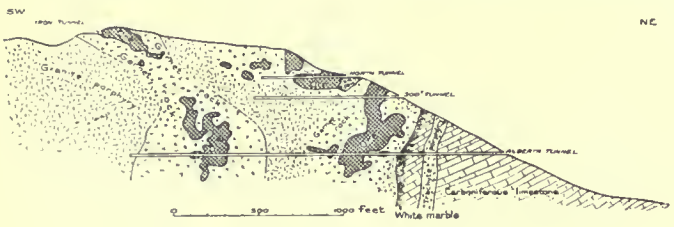
BONNER COUNTY

In a raise between No. 4 and 1 levels in the Idaho-Continental mine, 26 miles from Porthill, there is 6 ft. of high-grade and 6 ft. of mill ore. The raise is up 330 ft., and will be finished in 30 days. The 200-ton daily capacity concentrator has been completed, also the hydro-electric station on Boundary creek, midway between Porthill and the mine, together with the transmission line, and the entire equipment is ready for service at any time. The mill will start about July 15, and by August 1 crude ore and concentrate will be shipped. To facilitate handling this product, an aerial tramway, 1500 ft. long, will be constructed over the Kootenai river by the Riblett Tramway Co. Ore will be hauled to the river by 'caterpillar' engines and Troy 15-ton trailers.

CUSTER COUNTY

The genesis of the garnetiferous copper deposits near Mackay are described in the June issue of *Economic Geology* by Joseph B. Umpleby. The district lies at an elevation of from 5888 to 9600 ft. above sea-level. Rock formations are Carboniferous limestone, intruded by late Cretaceous granite porphyry, and trachyte porphyry. The orebodies occur within the main igneous mass, well back from its border. Most of the production has come from shoots of ore situated from 100 to 800 ft. out in granite porphyry, and two carloads was obtained from an orebody 1200 ft. back from the main igneous contact. No deposits of proved importance occur in the main limestone area. In places the orebodies are closely associated with large blocks of limestone included in the

igneous rock. Garnet rock accompanies all the important ore-shoots, and in most of the primary ore this mineral is the dominant constituent. The orebodies vary greatly in size, and even more in shape. Three principal groups are recog-



GEOLOGIC MAP AND SECTION OF A SMALL AREA SURROUNDING THE EMPIRE COPPER CO.'S PRINCIPAL DEPOSITS.

nized, one in the Copper Bullion and two above the Alberta adit. The primary ores consist of an intimate intergrowth of garnet and chalcopyrite, and the latter contains 5 to 6% copper, with a little gold and silver.

Shoshone County

A mortgage totaling $20,152 and covering the claims of 37 creditors of the Idora Hill Mining Co. has been placed on record at Wallace. The deed includes several mining claims and all tools, machinery, mills, and other equipment.

Annual meetings of the Moon Creek Mining Co., Aurora-Sampson Mining Co., Valentine Mining Co., and Four Timbers Mining Co. have been held, and the various properties owned were discussed.——A meeting of the Gertie Mining Co. was held at Spokane on June 20, when the capital was increased, and it was decided soon to begin driving a lower adit 3700 ft. long. The portal will be about 1000 ft. from the schoolhouse at Burke. A vertical depth of 1400 ft. will be obtained by the adit, which will cost from $50,000 to $65,000. A compressor plant is to be installed. A. A. Booth will be in charge of the work. The property is a promising one.——The Hercules Mining Co. will place in operation in its mines two 8-ton, 30-in. gage, 500-volt electric mining locomotives recently ordered from the General Electric Co.; and the Snowstorm Mining Co. at Larsen will install a 275-hp. induction motor and starting panel.——After an idleness of nearly two years, the result of litigation with the Bunker Hill & Sullivan company, the Caledonia mine, near Kellogg, has resumed operations. One of the stipulations in the compromise agreement that ended the controversy between the two companies was that a unit of the Bunker Hill & Sullivan mill should be set aside for the treatment of Caledonia ores. The plant has been under repair for several months and was given a trial run recently that proved satisfactory. The mill was started running one shift daily last week and is now treating about 100 tons per day. During the shutdown, connection by means of a raise was provided between the Caledonia workings and the long lower adit of the Bunker Hill & Sullivan, permitting the product of the mine to be handled through the latter at much less expense than under the former system of operating, and it is estimated that the Company now will average $40 to $45 per ton net on its ore. There is a large tonnage in sight in the mine, and engineers regard it as among the long-lived producers of the Coeur d'Alene lead-silver district. Charles McKinnis, one of the best known mining men in the Coeur d'Alene, is general manager of the Company.

NEVADA

Esmeralda County

The estimated production of the Goldfield Consolidated mine in June is as follows: Ore treated, 25,924 tons; gross extraction, $295,000; operating expenses, $155,000; and net realization, $140,000.——The Jumbo Extension company is now shipping 100 tons of ore per day to the Goldfield Consolidated mill.—A 20-ton cyanide plant, consisting of three 50-ton leaching vats, has been added to the Diamondfield Mining & Milling Co.'s 5-stamp mill. The ore averages $10 per ton.——More pumps have been ordered for the Atlanta mine. These are to be made by the Platt Iron Works of Dayton, Ohio, whose western representatives are C. C. Moore & Co. of San Francisco. The pumps are one Smith-Voile 6½ by 15-in. triplex, and one 6-in. Platt centrifugal, electrically driven. The total pumping capacity installed will eventually be 800,000 gal. per day.

Humboldt County

(Special Correspondence.)—On June 15, John F. Cowan of Salt Lake City, took his place as president of the Rochester Mines Co. The output of the property, from a depth of about 500 ft., is nearly $700,000, the ore averaging between $20 and $25 per ton. Recent work on the deeper levels has been encouraging. In the Codd lease, 4 ft. of ore was cut, 2 ft. of which is worth $35 per ton. At 800 ft. from the portal, the east vein has been cut in the main cross-cut.——The first shipment from the Rock lease on the Nenzel Crown Point property has given returns of better than $20 per ton.——About 8000 tons of good shipping ore has been developed in the Kahaler lease on the Weaver claims.——Four feet of $60 ore has been recently opened in the Buck and Charley lease in lower Rochester.——Regular shipments are being made from the Nevada-Packard lessees, Kromer and Hampton.——The Federal dredge which was sunk a few weeks ago, has been repaired and is again in operation.

Rochester, June 29.

Lander County

(Special Correspondence.)—The new camp of McCoy, found by Joe McCoy, about 17 miles southwest from Copper cañon, near Battle Mountain, is reported as promising. Gold ore is being opened, and also silver-lead ore. An engineer recently returned from this new find has described the geology roughly, as consisting of lime and porphyry lying on a granite floor, and intruded by dikes.

Battle Mountain, June 29.

Nye County

A new double-drum Nordberg hoist is being erected at the Wandering Boy shaft of the Jim Butler mine. The machine will be driven by a 125-hp. electric motor, and has a hoisting speed of 800 ft. per minute.——A larger yield is expected from the Montana-Tonopah in June. During the past week the mill treated 150 tons with 93% recovery.——The West End mill is treating 215 tons per day.——At 1100 ft. in the Extension, the Murray vein is 9 ft. wide, worth from $30 to $75 per ton.——The 1000, 1050, and 1130-ft. levels of the North Star are improving.

Storey County

All disputes on the Comstock lode have been settled, and development of the lower levels is now assured.——A tube-mill, Dorr classifier, and other machinery has arrived for the Yellow Jacket cyanide plant.

NEW MEXICO

Large gains were made in the production of gold, silver, copper, and zinc at mines in New Mexico in 1913, according to figures compiled by Charles W. Henderson, of the U. S. Geological Survey. The production of gold showed an increase of $97,480 over the output of $784,446 in 1912; silver, an increase of 94,572 oz. over the production of 1,536,701 oz. in 1912; lead, a decrease of 1,547,654 lb. from the yield of 5,494,018 lb. in 1912; copper, an increase of 22,277,742 lb. over the yield of 34,030,964 lb. in 1912; and zinc, an increase of 2,956,524 lb. over the output of 13,566,637 lb. in 1912. Despite lower average yearly prices for copper and zinc, the total value of the output was $11,694,002, an increase for 1913 of $3,166,047.

WASHINGTON

The mineral resources of this state, with statistics for 1912, are described in *Bulletin* No. 11, by Henry Landes of the Washington Geological Survey. The publication consists of 53 pages, with an index and a large map showing locations of certain minerals in the state. Other reports will be prepared from time to time. The following subjects are discussed: granite quarries, sandstone quarries, limestone and kilns, basalt quarries, sand and gravel pits, coal mining, clay, the cement industry, metal mining, and mineral waters. The output in 1912 and 1911 was as follows:

Metallic products.	1912.	1911.
Copper	$ 179,192	$ 39,776
Gold	680,964	847,677
Lead	5,732	38,186
Silver	254,326	129,204
Total metallic	$ 1,120,214	$ 1,054,843
Non-metallic products:		
Clay products	$ 2,388,870	$ 2,861,758
Coal	8,042,871	8,174,170
Granite	809,201	1,345,551
Lime	234,832	228,933
Limestone	20,370	32,478
Mineral waters	17,542	14,654
Portland cement	2,012,785	1,496,807
Sand and gravel	345,289	319,760
Sandstone	344,476	301,843
Total non-metallic	$14,216,236	$14,775,954
Grand total	$15,336,450	$15,830,797

Some excellent brick is made in this state, some of which is used for street paving. The clay industry is widespread in 18 counties.

The output of the gold, silver, copper, and lead mines in Washington in 1913, according to C. N. Gerry, of the U. S. Geological Survey, was valued at $1,053,135, compared with $1,120,214 in 1912. The decrease was due to lower metal prices and a smaller production of silver and copper. The gold output has a value of $696,275; the production of silver decreased from 413,538 oz. in 1912 to 331,239 oz. in 1913. The copper production likewise decreased from 1,086,010 lb. in 1912 to 954,081 lb. in 1913. Lead production increased from 127,387 lb. in 1912 to 202,487 lb. in 1913. There were 57 productive properties, of which 12 were placer and 45 lode mines.

Mining and industrial companies which are now operating in Washington, Idaho, and British Columbia, and tributary to Spokane, paid $565,386 in dividends during the first 10 days of July. Of this, $309,800 was paid by the Washington Water Power Co., which supplies power to mines in the Coeur d'Alenes; $123,836 by the Stewart Mining Co.; $81,750 by the Bunker Hill & Sullivan company; and $50,000 by the Standard Silver-Lead company.

Ferry County

After an idleness of nearly two years, mostly due to litigation, the Quilp mine, one of the oldest developed properties in Republic will resume operations. The decision to reopen the mine was made at a meeting of the directors this week in the offices of W. J. C. Wakefield of Spokane, vice-president of the Quilp Gold Mining Company.——Attempts to consolidate the San Poil Mining Co. and the Republic Mines Corporation, which is in the hands of a receiver, are being opposed by creditors of the latter Company.

Stevens County

The raise between the United Copper lower adit and the 600-ft. level, a distance of 465 ft. on the incline, was completed in 60 days, and was in ore all the way. Ore is to be stoped from the 1000 and 600-ft. levels.

UTAH

Juab County

Ore shipments from 16 mines at Tintic during the past week totaled 137 cars.——The Chief Consolidated company has paid another dividend of 5c. per share, equal to $43,822.——The Iron Blossom company will pay another quarterly dividend of 10c. per share, equal to $100,000. Ore shipments are about 150 tons per day from the 400, 500, and 600-ft. levels.

Summit County

According to the general manager, G. W. Lambourne, the Daly-Judge mine is in good condition. A drift is being driven at 300 ft. to cut an orebody opened to that point by a raise. The rich shoots in the Daly vein are continuing to the surface. These shoots are in the form of 'chimneys,' and are from 2 to 50 ft. wide, and 15 to 50 ft. high. On the 1200-ft. level a stope has yielded ore for a length of 235 ft., 20 ft. high and 25 ft. wide, all mill ore, containing lead and zinc. Development totals about 1000 ft. per month.——The Mines Operating Co. has shipped about 20,000 oz. silver, being part of the June clean-up. Formerly precipitate was shipped, but a refinery has been installed recently at the property.

COSTA RICA

The Abangarez Gold Fields Co. produced bullion worth $43,385 from 6588 tons of ore in April, at a loss of $3857. The loss for the first four months of 1914 was $64,706. Owing to difficulties experienced of late in getting sufficient profitable ore to run the plant, it has been deemed advisable to stop operations for the present and devote the attention of the staff to underground development.

KOREA

The Seoul Mining Co., operating the Suan Concession in Whang Hai province, reports the following results for June, 1914:

Stamps working	40
Time, days	27.83
Ore crushed, tons	5,960
Total recovery	$60,562
Operating expenses	25,000
Net earnings	$35,562

MEXICO

Chihuahua

The American Smelting & Refining Co. has decided to resume operation at the Chihuahua smelter, one of the largest of the Company's plants in northern Mexico. The Company's employees have been ordered to proceed to Chihuahua and it is expected that early in July the plant will be in full operation. It is also intended to blow-in the Monterey plant in Nueva Leon, and then the Velardena plant in Coahuila.

Sonora

During the last week of June, trouble started among employees at the Mines Company of America's La Colorado mine, near Hermosillo, who are dissatisfied with conditions, probably more politically than with the Company. The trouble spread to Cananea, more in the nature of a sympathetic strike which started on July 2. There is no dispute with the Greene Cananea company. Demands of the strikers are as follows: An increase in wages of 25%; a decrease in the price of goods at the Company store of 25%; abolishment of the new labor bureau; some changes in the management of the Company hospital; and that wages in future be paid weekly. George Kingdon, superintendent at Cananea, arrived at Douglas, Arizona, on July 2, and consulted with James Douglas, the general manager. The position was regarded as serious as mill and smeltermen left their work, but 2000 returned later on. There are 200 troops at Cananea to keep order.

PERSONAL

J. D. Irving has gone to Butte.

John W. Finch was in Salt Lake City recently.

C. P. Perrin sailed from Seattle for Japan on June 27.

Walter M. Henderson Scott has gone to England for a vacation.

R. H. Richards was at Ishpeming last week and has gone to Houghton.

Sumner S. Smith came down to Seattle from Nome last week and has gone north to Juneau.

C. D. Kaeding has been made vice-president and general manager for the Dome Mines Company.

Huntington Adams has gone to Chile, S. A., where his address is in care W. R. Grace & Co., Iquique, Chile.

Morton Webber has gone to Idaho to make a preliminary examination of a placer deposit for New York clients.

W. J. Pentland is in Denver, Colorado, where his address will be temporarily in care of Dorr Cyanide Machinery Co., Denver.

H. L. Smyth is to be the head of the combined school of mines of Harvard University and Massachusetts Institute of Technology.

Samuel Newhouse, formerly a prominent mining operator of Utah, but now a resident of New York City, is in Salt Lake City on a visit.

J. Vanophem, of Brussels, president of the Algunican Development Co., owner of the Jualin mine at Jualin, north of Juneau, inspected the property recently.

W. D. B. Motter, Jr., recently manager for the Canada Iron Mines, Ltd., of Trenton, Ontario, was appointed on May 1 as manager for the Benson Mines Co. at Benson Mines, New York.

Henry Tschetschott, professor of ore dressing and metallurgy at the Mining Institute of St. Petersburg, is in the Juneau district, Alaska, studying the methods of ore treatment.

J. A. Singmaster, general superintendent for the New Jersey Zinc Co., of Palmerton, Pennsylvania, is making a tour of Europe visiting smelters and other departments of the zinc industry.

John H. Blee, formerly underground superintendent for the Aurora Consolidated Mines Co., has accepted a position as superintendent of the Nau Aug mine, twelve miles from Hailey, Idaho.

E. E. Price, who has been superintending operations at the Lower Mammoth mine of the Tintic district, Utah, during the past two years, left recently for Casper, Wyoming, where he will take charge of the Pine Dome Oil Co.'s property. William Foyer will succeed Mr. Price.

H. G. Young has resigned as manager for the Trethewey Silver-Cobalt Mine, Ltd., and has accepted the position of consulting engineer to the Algunican Development Co. of the Juneau district, Alaska, and general manager for its subsidiary companies. Mr. Young will leave Cobalt about August 1.

Obituary

Frank Robbins, who for the past fifteen years had made his home in Los Angeles, died on June 21 of pneumonia, after a brief illness. In the early days of the Eureka district, Mr. Robbins was superintendent of the Eureka Consolidated. Later he was manager for mines at Valle de los Angeles in Honduras; MacKenzie and Mann at Greenwood, British Columbia; and also of the Elkhorn at Leadville, Colorado. He also held other important positions and his loss will be deeply regretted by his many friends in the mining profession.

Edward C. Limbach, superintendent of the American Girl mines at Ogilby, California, at 1 p. m. on June 15, slipped and fell upon the drive-belt of one of the Hardinge mills, passing around the pully on the countershaft. He died two hours later. Mr. Limbach was a graduate of the Colorado School of Mines in the class of '95, and followed the profession for a number of years in Colorado and Montana and later in Loomis, Washington, where his family are living. He was a man of charming personality, always well liked by his associates in school and in the field, honest, upright, and fair. He has improved the practice at the American Girl considerably in the short time he was there, and was a valued member of the profession.

Arthur Austin, chief testing engineer at the Tooele smelter of the International S. & R. Co., was severely burned June 29 while testing an oil burner for the assay furnaces. He was using a steel barrel containing fuel oil under high pressure. The head of the barrel blew out, covering him with oil which immediately took fire from a nearby flame. His injuries were so severe that he died a few hours later. He was a son of L. S. Austin, the well known metallurgist, and was himself well started on a promising career in metallurgy. After graduating from the Colorado School and the Michigan College of Mines he entered the service of the Anaconda Copper M. Co. in 1906, from which he was transferred to the International in 1911.

SOCIETY MEETINGS

JULY	
Northern California and Southern Oregon Mining Congress, Ashland, Oregon	9-10
AUGUST	
American Institute of Mining Engineers, Salt Lake City	10-14
British Association, Adelaide, South Australia	8
Canadian Mining Institute, Rocky Mountain branch, Banff.	
Lake Superior Mining Institute, Ishpeming, Michigan	31 to Sept. 3
SEPTEMBER	
American Chemical Society, Montreal	15-18
American Institute of Electrical Engineers	not fixed
Colorado Scientific Society, Denver	3
Illuminating Engineering Society, Cleveland	21-25
OCTOBER	
American Institute of Electrical Engineers	9
American Iron and Steel Institute	23-24
Colorado Scientific Society, Denver	3
NOVEMBER	
American Institute of Electrical Engineers	13
Colorado Scientific Society, Denver	7
DECEMBER	
American Institute of Electrical Engineers	11
American Museum of Safety	11-20
American Society of Mechanical Engineers	7-8

The University of Minnesota School of Mines, at Minneapolis, begins the first semester on September 1, with 58 instructors in the faculty. There are three regular courses of study, namely, mining engineering, mining engineering specializing in geology, and metallurgy, leading to the degree of engineer of mines, engineer of mines in geology, and metallurgical engineer, respectively. The bulletin of June 1914 describes the courses and other general information.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 9.—A large business is being done in copper in both domestic and export trade, but local buyers' requirements are not well covered. The price has moved up steadily all the week. Lead and spelter are quiet. Tin is steady at 31.90 to 32c., and antimony is dull at 7.12 to 7.25c. In London, copper is steady at £62 6s.3d. to £62 12s.6d., tin steady at £144 15s. to £146 5s., and bar silver steady at 25⅞d. The American Smelting & Refining Co. is having trouble in starting up its Chihuahua plant.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask

or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement for June shows a decrease in production and increase in stocks on hand. The details are as follows:

	Pounds.
Stocks of marketable copper of all kinds on hand at all points in the United States, June 1, 1914	84,342,611
Production of marketable copper in the United States from all domestic and foreign sources during June	141,310,000
Deliveries for consumption, June	45,927,000
Deliveries for export, June	73,350,477
Stock of marketable copper of all kinds on hand and at all points in the U. S., July 1	97,142,863

Recent changes in surplus have been as follows, in pounds:

	Increase.	Decrease.
June 1913	.....	14,569,619
July	690,330	.....
August	.....	15,280,908
September	.....	8,531,043

April	5,727,682	.....
May	14,005,640	.....
June	12,768,022	.....

COAL AND COKE PRODUCTION

The following data, covering 1913, is from the U. S. Geological Survey:

	Miners employed.	Coal mined, tons.	Value.	Coke made, tons.	Value.
Alabama	.....	.....	$.....	3,323,664	$ 9,627,170
Arkansas	4,660	2,234,107	3,582,789	.....	.....
Illinois	.....	.....	.....	1,859,553	8,593,581
Indiana	.....	.....	.....	2,727,025	13,182,136
Iowa	15,679	7,490,641	13,431,061	.....	.....
Kansas	12,479	7,202,210	12,036,292	.....	.....
North Dakota	.....	495,320	750,652	.....	.....
Tennessee	11,263	6,903,784	7,883,714	.....	.....
Texas	.....	2,429,144	4,288,920	.....	.....
Virginia	9,162	8,828,068	8,952,653	.....	.....

Each of these states produced more coal than in 1912. Alabama coke output was 348,175 tons over the previous year, and this increase was from by-product ovens. These yielded 2890 tons per oven, against 212 tons from the beehive type. Coke made in Illinois and Indiana comes from West Virginia mines. Iowa is primarily an agricultural state, and excepting the coal used by railroads, the sale depends on rural communities. Kansas operators had little to complain of in 1913. The North Dakota output is all lignite. The year was satisfactory in Tennessee. Texas produces lignite and bituminous coal in equal quantities.

PRODUCTION of abrasive garnet in the United States in 1913 amounted to 5308 short tons, valued at $183,422, according to the U. S. Geological Survey. This was the largest in the history of the industry, and an increase of 361 tons in quantity and of $20,185 in value, compared with the production for 1912. The industry was confined to three states, New Hampshire, New York, and North Carolina.

TIN STATISTICS for June show the following movements, according to L. Vogelstein & Co. of New York: Shipments of standard metal to America, England, and Europe, 7894 tons; deliveries, 8995 tons; visible stocks, 18,562 tons; average price, 30.60c. per lb. Figures for May were 11,744,887, and 19,663 tons, and 33.25c. respectively.

BULLION received at the San Francisco mint during June was as follows: Gold, 143,156 oz. worth $2,959,303; and silver, 21,632 oz. worth $12,114. The coinage executed was $3,000,000 in double eagles, and $21,500 in one-cent pieces. Coin, bullion, etc., on hand at the end of June amounted to $246,370,370.83.

THE LAKE SUPERIOR MINING INSTITUTE will hold its nineteenth annual meeting at Ishpeming and Detroit at the end of August and beginning of September. A first-aid demonstration will be held, and the mines visited at Ishpeming.

ARTIFICIAL GRAPHITE manufactured at Niagara Falls in 1913 was valued at $973,397.

COMPANY REPORTS

INTERNATIONAL NICKEL COMPANY

The twelfth annual report of this Company for the financial year ended March 31, 1914, shows gross profits amounting to $6,366,786. After deducting depreciation, 'exhaustion of minerals,' and all other charges, the net profits amounted to $4,792,665. Dividends on the preferred and common stocks to the amount of $4,337,906 were paid, and the sum of $454,759 was carried forward. The assets of the Company are placed at $53,941,207, of which $9,210,442 are current assets, cash on hand being $3,243,673. During the year, the unsatisfactory conditions prevailing in the steel industry, coupled with lower prices received for the output of copper, resulted in the earnings being slightly less than for the previous year. Many improvements have, however, been made in the smelter and at the mines which will result in a greater output at lower costs. The benefit of these expenditures will probably be felt during the present year.

HAMPDEN CLONCURRY COPPER MINES, Ltd.

The report of this Queensland Company covers the half-year ended February 28, 1914. In the six mines, a total of 3187 ft. of development was done. The Duchess shaft was sunk to 727 ft. Three winzes, sunk below the 550-ft. level, have opened 18 to 20% ore at depths of 97 to 126 ft. Reserves in this mine are estimated at 67,000 tons. At 350 ft. in the Hampden, a sulphide orebody has been opened for 220 ft., it being from 4 to 9 ft. wide, averaging 10% copper. This ore contains less than 20% silica. No. 1 shaft was sunk to 523 ft. A low-grade shoot was cut at 490 ft., and driving at 500 ft. has opened ore assaying 10.1% silica, 51.2% iron oxide, 39.1% sulphur, and 3.8% copper. Reserves total 57,000 tons. Seven per cent ore was opened at 200 ft. in the Trekelano mine. Reserves in all mines are estimated as 241,000 tons averaging about 10% copper. Ore smelted was 33,105 tons producing 6,885,760 lb. copper, 1023 oz. gold, and 26,172 oz. silver. The revenue was £222,158; profit, £65,847; and dividend, £35,000.

LUCKY TIGER-COMBINATION GOLD MINING COMPANY

This Company has its general office in Kansas City, Missouri, and controls the Tigre Mining Co., which operates mines and mills at El Tigre, District of Moctezuma, Sonora, Mexico. The report covers the calendar year 1913. The reports of the consulting engineer, James W. Malcolmson, and general manager, L. R. Budrow, contain the following information:

Development totaled 4984 ft., of which 2400 ft. was diamond-drilling, the latter cutting the Keiley vein on No. 3 level 150 ft. east of the main vein. No. 2 level cut this shoot, which has developed about 300 ft. of a good grade of ore. Cross-cuts were driven on No. 1, 3, and 3½ levels to cut the vein. No. 3 reached it, and 89 ft. of driving was done in ore. The other cross-cuts have since cut the vein. Stoping was started on this vein in February, 1914. Work on the main Tigre vein totaled 2291 ft., and on the Sooy vein, 39 ft. Development cost 59.2c. per ton. There was 56,081 tons of ore broken, of 9.2c. per ton. Concentrate produced was 2358 tons, assaying, 0.493 oz. gold, 285 oz. silver, 2.32% copper, and 12.05% lead. Broken ore in stopes amounts to 28,907 tons. Mining cost $2.80 per ton.

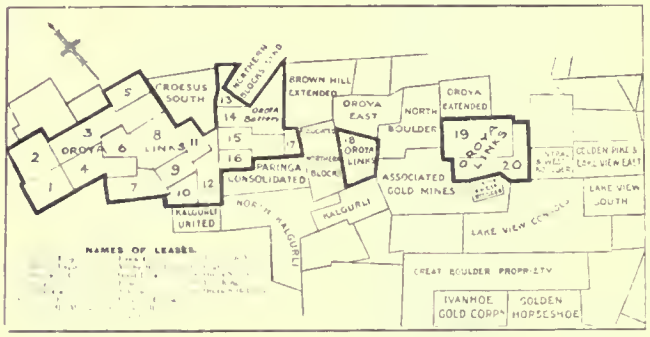
The mills crushed 68,528 tons of ore, and the cyanide plant treated 64,757 tons of current and 21,778 tons of dump tailing, at a cost of $3.99 per ton. Ore transport to the mills cost 9.2c. per ton. Concentrate produced was 2358 tons assaying, gold, 1.85 oz.; silver, 351.18 oz.; lead, 6.6%; and copper, 1.53%. The mills yielded 4199 oz. gold and 1,220,028 oz. silver, valued at $811,456. The total recovery was 92.8%. By shutting down the old mill a saving of about $2500 per month will be made. The gross value of ore milled and shipped was $1,577,526, or an average of $21.85 per ton.

Net realization from operations was $729,657, and including cash at the beginning of 1913, the total available was $871,077. Out of this, 12 dividends were paid totaling $450,662, and the cash on hand at the end of the year was $125,943.

OROYA LINKS, LIMITED

As will be seen from the accompanying map, this Company controls a large area at Kalgoorlie, Western Australia, on which it is doing a considerable amount of work, also 50 tributers or lessees, who mostly worked in the oxidized ores. The report covers the year ended December 31, 1913. The superintendent is P. Fitzgerald, and general manager, Bewick, Moreing & Company.

Development in the various claims totaled 5960 ft., also station cutting and surface trenching. The expenditure was



CLAIM MAP SHOWING OROYA LINKS PROPERTY AND OTHER PRINCIPAL MINES AT KALGOORLIE.

£14,526, equal to 50c. per ton milled. A good deal of work was done at and above 750 ft. in the Eclipse mine; the Croesus Proprietary shaft was sunk from 750 to 935 ft. (now 945 ft.), the lode being cut at 932 ft.; work was confined mainly to the oxidized portion of the Brownhill west lode; and in the Oroya north block, the Magazine lode worked by tributers was followed down to the boundary in rich ore, but above 110 ft. there was nothing of importance disclosed. Ore reserves are estimated at 146,775 tons worth $5.82 per ton, an increase of 32,466 tons and 16c. per ton in value. Tributers on nine claims mined 4183 tons of ore yielding £9589, on which the royalty was £1831. Results were as follows:

Ore extracted from five mines (Eclipse and Oroya North mainly), tons	139,130
Gold from 50-stamp mill, slime and concentrate plant, etc.	£151,819
Net profit in Western Australia	15,899
Forward to 1914, including balance from 1912	18,180
Cash at bankers, in hand, and on loan	61,916
Total cost per ton	$3.86

During the first quarter of 1914, 35,630 tons of ore was treated at a profit of £4826.

INSPIRATION CONSOLIDATED COPPER COMPANY

The Inspiration property in Gila county, Arizona, is the scene of great activity. Aside from mine development, a mine plant, a 10,000-ton concentrating plant, and the testing of the flotation process at the rate of 600 tons per day is under way. The report of the general manager, C. E. Mills, covers the year 1913. The property now totals 2857 acres. Underground preparation for ore extraction continued,

and development totaled 37,760 ft., making a total of 110,609 ft. to date. There was hoisted 47,200 tons of 1.86% copper ore, and 196,783 tons of waste. Ore on hand in stockpiles amounted to 195,000 tons, averaging 1.79%, at the end of the year. In the Live Oak claims 17 holes were drilled an average depth of 241 ft., and 6,858,000 tons of carbonate and sulphide ores, assaying from 1.33 to 1.45%, was developed. Churn-drilling has been very satisfactory. Reserves are as follows:

Class of ore.	Tons.	Copper Per cent.
Sulphide	45,000,000	2.00
Low sulphide	28,322,000	1.26
Oxidized	12,445,000	1.34
Mixed carbonate and sulphide	3,876,000	1.24
Total	89,643,000	1.64

Mining operations will probably be confined for many years to the higher-grade ore.

Surface equipment at Inspiration for a capacity of 10,000 tons per day is as follows: Steam power-plant of three 6000-kw. generators, head-frames for two main shafts and receiving bin of 2000-ton capacity, two electric hoists of the Ilgner system, air-compressors to supply 11,000 cu. ft. per minute for mine drills, high-pressure compressor for underground locomotives, coarse crushing plant with four No. 8 gyratory crushers and eight 48-in. disc grinders, ore storage bins on railroad at mine to hold 25,000 tons, ore-bins at mill to hold 12,000 tons, concentrating plant 1½ miles from mine, water supply plant of 5,000,000 gal. daily capacity, and 7¼ miles of standard-gage railroad to the mine, mill, smelter, and connecting railroad. The plant should start at the end of 1914.

To provide the funds necessary for extensions to original plans, etc., five-year 6% convertible debenture bonds, amounting to $4,500,000 were authorized. Assets totaled $20,586,996, including $1,781,146 cash. Liabilities include accounts payable, $127,836; and 10-year 6% convertible bonds, $6,000,000.

MOUNT LYELL MINING & RAILWAY COMPANY, LTD.

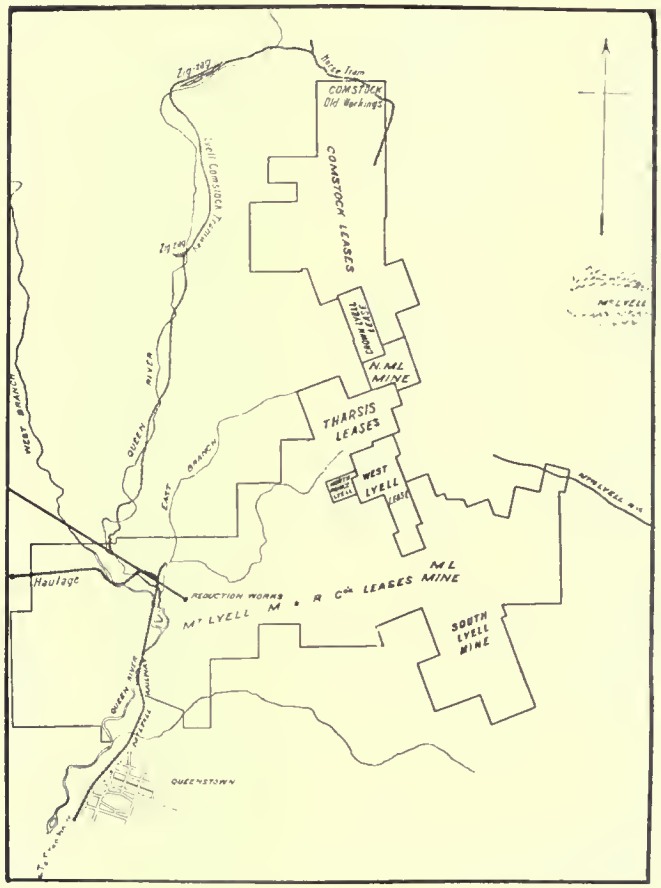
The report of this Tasmanian company covers the half-year ended March 31, 1914, and is replete with data on mining, smelting, and new power scheme; with photographs, plans of the district, and of the North Lyell mine. The combined reports of the general manager, Robert C. Sticht; engineer in charge of mines, R. M. Murray; local superintendent, Basil Sawyer; metallurgist, R. P. Roberts; chief mechanical engineer, G. W. Wright; superintending engineer of railways, E. Carus Driffield; and engineer for supplies, Huntley J. Clarke, contain the following information: At the Mt. Lyell mine, overburden was removed from benches No. 2a, 3a, 3b, 4c, and 5. Ore was broken from No. 4 bench. Only 19,934 tons was taken from the open-cut. No. 6, 7, and 8 levels underground were actively worked producing 88,507 tons. Diamond-drilling 545 ft. yielded promising results. This mine supplied 5021 tons of pyrite (45% sulphur) for the Company's chemical works in Australia. Ore reserves in the parent mine amount to 2,097,072 tons averaging 0.531% copper, 1.96 oz. silver, and 0.0275 oz. gold.

Prospecting was done in the south Mt. Lyell mine.

The north Mt. Lyell mine produced 60,461 tons of ore, and 120 tons of copper precipitate from underground water. A station was cut at the 1100-ft. level for a new hoist winze being sunk to open the orebodies below this level. Work was also started to connect the 200, 700, and 850-ft. levels with the Crown Lyell shaft. Ore reserves in the North Mt. Lyell are 1,025,651 tons averaging 6% copper, 1.33 oz. silver, and 0.005 oz. gold.

Prospecting was done on five levels in the Lyell Comstock mine. Development in all mines totaled 4531 ft., including 1836 ft. of drilling. The blast-furnaces treated a total of 163,513 tons of ore, fluxes, etc., Mt. Lyell supplying the basic, and North Mt. Lyell the silicious ore. The average mixture smelted contained 2.49% copper, 1.62 oz. silver, and 0.028 oz. gold. From 9360 tons of matte, there was produced 3433 tons of blister copper, assaying 98.78% copper, 67.5 oz. silver, and 1.312 oz. gold per ton, equal to 3391 tons of copper, 231,740 oz. silver, and 4504 oz. gold. Costs were as follows: Mining, $2.43; smelting, $2.13; and converting, 30c., a total of $4.86 per ton, against $5.32 in the previous term.

After deducting all charges, the net profit was $298,000. With the balance from the previous half-year, the amount available was $2,980,000, out of which $385,000 was paid as dividend No. 17 of 30c. per share. On June 15, 1914, No. 18 was paid, amounting to $300,000, or 24c. per share. Assets show a surplus of $1,680,000 over liabilities.



PLAN OF MT. LYELL PROPERTY AND DISTRICT. THE NEW POWER PROJECT IS SITUATED A FEW MILES NORTH.

Rainfall at various points in the district was from 31.18 to 68.28 in. on 87 to 119 days. Good progress is being made with the Lake Margaret hydro-electric scheme, the plant being well under way, and all transmission poles erected. Power should be available in September, 1914.

An experimental plant has been erected at the smelter to test ore by flotation methods. Trials on North Mt. Lyell ore have been made, and those on Lyell Comstock were satisfactory.

The three chemical and superphosphate plants in Australia operated in the usual satisfactory manner. The South Australian interests were amalgamated with those of the Wallaroo Phosphate Co., Ltd., and a new company registered. The railways were kept in good order, the revenue being $97,000, and expenditure $77,000.

The Company's metal production since August, 1903, is: Copper, 127,498 tons; silver, 10,626,593 oz.; and gold, 321,104 ounces.

RECENT PATENTS

1,097,336—Electric furnace working with an electric arc or arcs for melting and extraction of metal from ore. Peter Krefting, Christiania, Norway.

An electric furnace comprising a closed melting chamber, a vertical charging shaft above the chamber, provided with a plurality of extensions with charging apertures, said apertures being normally closed by the charging material, a flue leading from the melting chamber through the material being charged, said flue extending through the shaft, and a plurality of electrodes extending into the melting chamber substantially as described.

1,098,282—Process for treating so-called carnotite and associated and similar vanadium and uranium minerals. Herbert N. McCoy, Chicago, Illinois.

A process of treating carnotite and allied ores, consisting in heating the ore in presence of sulphuric acid until a mass is obtained which is solid when cold and which contains substantially all of the vanadium and uranium in a readily soluble condition, extracting the soluble constituents from the said mass, treating the solution thus obtained to recover the values therefrom, and treating the residue for the concentration of its radium content.

1,098,183—Ore concentrator. John L. Signorette, Los Angeles, California.

In an ore concentrator, the combination with a base, of resilient supports carried by said base, a tray mounted on the support, a longitudinally extending bumper bar connected with the bottom of the tray, a standard mounted on the base adjacent to each end of the tray, resilient means for reciprocating the tray, means carried by the standards adapted to be engaged by the bumper bar during the reciprocation of the tray to jar such tray and independent adjusting devices for the resilient means and last-mentioned means whereby the shock at either end of the reciprocation may be regulated.

1,100,217; 1,100,218; 1,100,219; 1,100,220; 1,100,221; 1,100,222; and 1,100,223 have been granted to Charles Butters, Oakland, California, covering apparatus for filtering slime. This includes, respectively: (1) a suction filter-leaf having means for admitting water thereinto to dislodge a cake therefrom, and a relief valve in communication with the upper portion thereof to relieve said leaf of air as water is admitted thereto; (2) in a suction filter-leaf, the combination of a frame filter media carried thereby and a water-supply pipe for cake-dislodging purposes connected to said leaf, said pipe having an opening to atmosphere near its point of attachment to the leaf; (3) a filter-leaf having means for equalizing the external and internal water pressure thereon while said leaf is submerged; (4) a suction filter-leaf having a manually operated valve connected with a submerged portion thereof; (5) the step in the process of treating slime which consists in running water through the filtering means while submerging said means in the slime; (6) a filter-leaf having a header, a frame, filter media mounted on said frame and supported by said header, and a perforated pipe mounted on said leaf above said header; and (7) the process of dislodging slime cakes from filter-cloths, which consists in saturating without pressure substantially the entire surface of the cloth while the cake is thereon. Patent 1,100,267, consisting of a filter medium for a suction filter-leaf open across the bottom was granted to William Arma Stedman, of Wonder, Nevada, assignor to the Butters Patent Vacuum Filter Co., a corporation of Nevada.

Mining Advance Into the Inland Empire. A comparative study of the beginnings of the mining industry in Idaho and Montana, eastern Washington and Oregon, and the southern interior of British Columbia; and of institutions and laws based upon that industry. By William J. Trimble. A thesis submitted for the degree of doctor of philosophy at the University of Wisconsin. P. 254. Map. Madison, Wisconsin. Price, 40 cents.

Coal, Oil, Gas, Limestone, and Iron Ore Map. Revised edition by the West Virginia Geological Survey, February 1, 1914. It contains a thorough revision of the coal, oil, and gas developments, several anticlinals being added and others corrected from later observations. The names and addresses of 918 coal companies operating in the state are given by counties, as well as the locations of their mines. The names of many new towns, post-offices, etc., are added, and the valuable iron ore deposits of the state are also indicated on this map, and all the special features of previous editions corrected and brought up to date, showing the approximate areas of the several coal series, as well as the oil and gas pools. Scale 8 miles to the inch. Price, enclosed in strong envelope and delivered by mail, 50c. each.

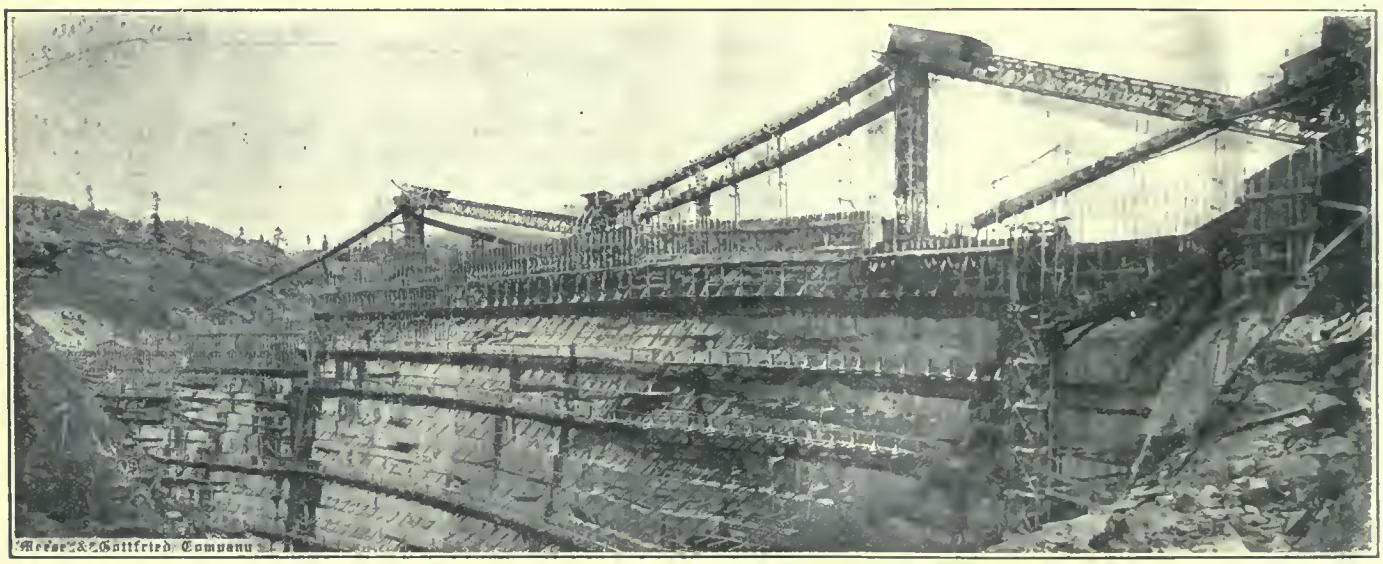
Kanawha County. By Charles E. Krebs, D. D. Teets, Jr., W. Armstrong Price, and I. C. White. West Virginia Geological Survey publication. P. 679. Ill., maps, 38 plates, index. Morgantown, 1914. In addition to the description of the Kanawha coal series and all the geologic features of the county, the geologic map gives the structural contours on the Pittsburgh coal horizon north from the Kanawha and Elk rivers, and on the Kanawha Black Flint south and east of the Elk and Kanawha rivers, as also the location of the anticlines and synclines showing their relations to the several oil and gas pools of the county. The soil map and report of the experts of the U. S. Department of Agriculture covering this region of the state should prove of especial value to the agricultural and horticultural interests. Price, with case of maps, delivery charges paid by the survey, $2.

New Machines and Devices

A New Use for Belt Conveyors

Using a belt conveyor for the rapid transportation of wet concrete is quite a new departure and especially so is the elevation of such material on belt conveyors, owing to the tendency of the water to separate out and run back. However, by speeding up the belt to over 400 ft. per minute this tendency is overcome and the success of this method can be appreciated through the fact that over 2000 cu. yd. of wet concrete were thus conveyed to the forms in a working day of 10 hours in the construction of the Pacific Gas & Electric Co.'s dam at Lake Spaulding.

The concrete is mixed in a house on the mountain side, not shown in the illustration, where five one-yard mixers of the revolving drum type are kept in constant operation, which discharge the mixed concrete directly upon the horizontal belt conveyor traveling at a speed of about 400 ft. per minute. This conveyor discharges into a gravity chute leading down the hillside to the first elevating belt conveyor, which carries it upward at an incline of 18° to a tower erected on the dam, from which it is chuted down to another belt conveyor, operating at an incline of about 15° and again carried up to the final gravity chute. The conveyors used in this installation were furnished by the Meese & Gottfried Company of San Francisco, through whose courtesy the halftone is also presented.



BELT CONVEYORS HANDLING CONCRETE AT LAKE SPAULDING DAM.

The Fulton Iron Works of St. Louis, Missouri, in Bulletin 'A' describe the Fulton-Tosi oil engines, which are a high compression Diesel type engine. This particular engine is built in the vertical form and with two, three, and four cylinders. It is claimed the engine may be started from cold within one minute without any trouble or time consuming preliminaries. The points of advantage claimed for this particular engine are the open 'A' frame construction, permitting easy access to main bearings; the cylinder is cast in the form of a removable liner from hard iron; all valves are in separate cages and in the cylinder head; timing as well as fuel valve may be varied while the engine is in operation; starting valves are operated by air; a direct connected injection air compressor forms an integral part of the engine; and a continuous system of lubrication with a filter and cooler in circuit is a part of the equipment. The engine is adapted to all classes of fuel oil.

Autotraction Drill Rigs

The drilling of deep blast holes of relatively large diameter is coming to be more general practice in the conduct of all large mining operations, in railroad work, quarries, and all classes of large excavations. To meet the demand for drill rigs to drill deep vertical blast holes the Sullivan Machinery Company offers the autotraction drill. The purpose of this machine has been to serve the public with a drill which will drill deep holes faster and at a less expenditure of labor and power than the heavy tripod or cable drills, which are the two methods in common use. Toward this end the Company has designed the autotraction drill which permits of the length of run or feed of from 10 to 20 feet, thus obviating the frequent stops necessary to insert longer steel in the well-known tripod types. Another advantage claimed for this drill for deep hole work is the ease and speed with which the autotraction drill can be moved from a completed hole to the site of a new one. The moving of a $4\frac{1}{2}$ or 5-in. tripod drill, as those with experience will appreciate, is a slow job requiring several men. As compared with drills of the cable or well-boring type, the autotraction machine, with its reciprocating air or steam-driven piston is claimed to be a much faster driller. These outfits consist of a vertical standard or carriage, carrying a rock-drill cylinder attached to a heavy iron recoil block, which is suspended in guides, or ways, by steel cable passing over a sheave and alternately paid out or taken in, as needed, by a hoisting drum. The standard and hoist are mounted on a wagon truck made of structural steel. A 2-cylinder reversible engine provides power for the hoist and for moving the outfit from place to place.

AN 'absolutely new discovery' in metallurgy heralded some time ago as the Clapp process, which would make "extraction recoveries as follows: copper ores, 96 to 99.6 per cent; nickel, 99.6 per cent; iron and lead, 96.7 to 99.6 per cent," and would "revolutionize mining in the Western states," for some unknown reason has failed to revolute. There must be a reason.

THE passing of Victoriano Huerta from Mexico's political arena marks another change in the aspect of Mexican affairs. In that no good could possibly result to the Mexican people from his continuance in office, with revolution, secession, and bankruptcy ever upon the ascendency, it can only be hoped that in the reconstruction which now seems pending, broader political foundations, which will meet the requirements of the mass of the people, will be laid and peace will ensue. *Adios* Don Victoriano *y salud a su sucesor.*

HALF-WATT NITRO LAMPS, the latest development in the field of electric lighting, according to report bid fair to modify the present methods of illuminating. The advance which this new lamp marks may be better understood by a comparison of efficiency with the time-honored carbon filament and its current consumption of over six watts per candle-power. The new half-watt nitro lamp is of the tungsten filament variety with the bulb filled with nitrogen gas. At present the lamps range in size from 600 to 5000 candle-power, but with the perfection of methods of manufacture it may be expected that the half-watt nitro lamp, which is equally suited to both alternating and direct current, will be available in all of the commercial sizes.

DECORATION of Mr. Charles F. Rand with the Order of Isabella by the King of Spain is a pleasing recognition of his humanitarian and other services in Cuba during the Spanish-American war. It almost makes us regret that America has no official 'Order of Merit,' since it could so worthily be bestowed upon Mr. Rand as recognition from our side of his equally great work in the interest of sanitation and improvement of living conditions in time of peace. We shall have the pleasure shortly of printing a description of this work written by Mr. Rand himself. The able president of the Spanish-American Iron Company is an exponent of successful business on the highest plane, and we are glad to congratulate him upon an honor worthily won.

ANNUAL drilling contests, which are the ancient sport of the mines and have long formed the chief attraction in many of the mining camps on the Fourth of July, were in evidence this year as usual. Results are recorded in the 'Mining Summary' of this issue. While first-aid contests have come to divide attention, brawn, drill-steel, and granite continue to hold the centre of the stage.

SCRAP METALLURGIST is a degree not conferred by any of the accredited technical schools, but is nevertheless a real vocation amounting to a profession, according to Mr. William Jacobus, the original 'scrap metallurgist.' While most of us will associate the 'scrap metallurgist' with the 'ragman,' we must admit that Mr. Jacobus is worthy of an S.M. at least, if he has saved the Navy Department $2,000,000 a year by the institution of his methods in disposing of scrap metal.

WHILE the Australian Labor Federation is debating the feasibility of insisting upon the dismissal of all non-union men from the Australian goldfields, the Chamber of Mines of Western Australia announces that it will close every mine in that region rather than be dictated to by labor unions. Mine operators and labor have always maintained amicable relations in this district having met in convention every three years and adopted a labor agreement. It is to be hoped that this policy may be continued and a crisis avoided, since if the business of mining continues it must be at mutual profit of men and operators.

MINERAL LANDS on Indian reservations is the subject of a bill recently passed by the United States Senate. According to the new regulation, all lands containing the minerals, kaolin, kaolinite, fuller's earth, china clay, and ball clay, within such parts of Indian reservations as have heretofore been opened to settlement and entry under acts of Congress which did not authorize the disposal of such mineral lands, shall be open to exploration and purchase and be disposed of under the general provisions of the mining and coal-land laws of the United States, and the proceeds arising therefrom shall be deposited in the treasury. Senator Sterling of South Dakota, who proposed the bill, claims it to be of considerable importance to his state, in that deposits of fuller's earth of economic importance await such action to be profitably exploited. Recent produc-

tion statistics of the United States Geological Survey show the production of fuller's earth in 1913 to have been 38,594 tons, valued at $369,750, which is an increase of about $65,000 over the preceding year. The imports of fuller's earth during the year totaled $146,001.

THE Committee on Mines and Mining, to whom was referred the bill to provide for a commission to codify and suggest amendments to the general mining laws, has reported it back to the House of Representatives with the recommendation that the proposed code shall not deal with lands containing deposits of coal, oil, gas, phosphates, or soluble potassium salts, and that the bill be passed as amended. This amendment was suggested for the reason that the deposits named occupy a somewhat different status from the other minerals with respect to formation, methods of mining, and their use. The Department of the Interior has recommended legislation peculiarly adapted to the development and disposition of coal, oil, gas, phosphates, and potassium, which bills are now pending before the Senate and House committees on public lands. In the event of this bill being passed, which seems highly probable, there will undoubtedly be a commission created to make a thorough and exhaustive investigation of the subject and report its conclusions to Congress. The time is opportune for a discussion of the proposed revision, and we therefore take pleasure in presenting a discussion of the subject by Mr. F. R. Ingalsbe under the title of 'The Mining Law—Proposed Revision,' together with another contribution written by Mr. Clarence K. Colvin. Both recognize the importance of the subject, and their different viewpoints are both interesting and timely. We trust that a complete discussion of the subject will bring out the opinions of those interested so that revision may be undertaken with full knowledge.

THE American Petroleum Society, which was organized to promote the science of petroleum technology, gives promise of becoming a most useful organization, and it is to be hoped that the membership campaign now being conducted will meet with the hearty response of those interested either directly or indirectly in the production and use of petroleum, bitumen, and gas. The importance of the oil and gas industry is evidenced by the value of the production in the United States last year, which amounted to over $250,000,000, approximately 71 per cent of the world's supply. In 1907 the technologic branch of the United States Geological Survey, acting under authorization of Congress, undertook a comprehensive study of petroleum and its products, which work was and is being continued by the Bureau of Mines. It became evident to those in charge of the work that without the coöperation of the many men engaged in the industry and the funding of their knowledge for the advancement of the industry, this study would lose much of its effectiveness. The object of the Society is to consider, primarily, subjects relating to the science and technology of petroleum and its products, with the purpose of investigating those phases of the subject which are of direct and pertinent value to the industry, to join the wisdom of the scientist to the knowledge of the practical oil man for the advancement of the industry. In that the leading petroleum associations of the United States plan to make this society the arbiter of standards for the trade, it at once gains a prestige which other new societies of the other industries might only hope to attain after years of organization. At the present time there are not only a number of individuals but there are about 44 different committees in 43 different societies in the United States which are investigating subjects pertaining to petroleum with no forum available for the general discussion of this subject. That there is a need for this society is apparent and its success as an organization should be assured. The first annual meeting will be held in New Orleans on October 15, 1914, and the second in San Francisco from October 25 to 30, 1915, where the Society will act as host at a World's Petroleum Congress.

LEAD POISONING

Lead poisoning as contracted by employees of the smelters and refineries in the United States has recently been the subject of investigation by the Department of Labor. While the results of the investigation are largely statistical, they show conditions at the works toward correction of which real effort should be made. At the 19 plants, employing about 7400 men, investigated in the United States there were no less than 1769 cases of lead poisoning during the year 1912. From the cases reported it is seen that the exceedingly high figure of 22 per cent of the employees at these plants have been afflicted with lead poisoning. The hospital records at nine plants showed that 5 per cent of the employees were afflicted with this malady.

Of the plants investigated there were three which used blast-furnaces and large flue systems. While these plants employed only about 1000, or 13.5 per cent, of the total 7400 employees involved in the investigation, there were 387 cases of poisoning reported at these smelters. The figures presented may be, and probably are, in some instances exaggerated, as there is a tendency among workmen to attribute all of their ills to their vocation, regardless of origin, but it cannot be denied that there is an unnecessarily high percentage of men poisoned and a stronger effort toward reducing the prevalency of this disease should be made.

Lead poisoning became a very serious problem with the Austrian ore hearth workers in 1889, when there were 14 cases of lead colic among 61 men at one smelter. A change in working conditions whereby the hours of labor were reduced, four men working alternately in pairs for two hours at a time during each 12-hour shift and having rest periods of 24 hours between, resulted in such improvement that in 1902 and 1903 not a single case was recorded among the 49 men employed at the

same smelter. In Great Britain in 1912 there were only 37 cases of lead poisoning among 2009 men employed at lead smelters, or less than 2 per cent.. In Austria and Germany conditions are said to be less favorable. The governments of these countries are at present regulating this phase of the industry and a marked improvement is reported in recent years. The experience at the Port Pirie smelter in Australia is also worthy of notice. Here, a number of years ago, lead poisoning was exceedingly prevalent and the management undertook investigation and correction of existing conditions which has practically eliminated the disease. In addition to reducing smelter fume and dust to the minimum, the Company made it a rule, and this is important, that every man wash before eating.

In order to prevent lead poisoning, the coöperation of the men is as essential as is modern construction with every possible means of preventing dust and fume, and adequate sanitary appliances. Most operators agree that it is one thing to provide sanitary facilities for the men in the way of change rooms, wash rooms, dust-free lunch rooms, respirators, and the like, and it is another to get the men to take advantage of these facilities. In the majority of cases the laborer is lax, and the only remedy is a rule making violation of sanitary regulation cause for dismissal. The matter is largely one of habit, and when the men see results of these regulations in the form of a decreased number of cases of lead colic they will realize their value.

SULPHUR PRODUCTION

One of the curious things about mining is that while the production of certain mineral substances is generally regarded by everyone as the application of that ancient art, the exploitation and extraction of certain other substances, no less truly mineral, is scarcely considered, even by the profession, as being really mining. Roughly speaking, the digging of metallic mineral out of the ground is true mining; the digging of a non-metallic mineral (excepting coal) is something else. Conversely, if a substance is desired for its metal content, its digging is mining; if a non-metallic constituent is the object of the quest, its extraction from the ground usually fails to rise above the level of quarrying. Possibly one reason why quarrying is considered less dignified than mining is that a 'porphyry copper' is operated by a highly paid and efficient staff, while a quarry struggles along with ordinary laborers, paid about $2 per day, under the direction of a $250 per month superintendent, who nevertheless manages to keep operating costs down. Similarly, the small size of the producing units may be the reason why the digging of the 350,000 tons of pyrite each year produced in this country for its sulphur content does not usually come to mind in a hasty review of the mining industry of this country. The production of sulphur, whether from ore containing the elemental substance, from barren pyrite, or from the copper-bearing pyrite of Spain, is at least a distant relative of real mining, and one that can scarcely with good grace be relegated to the back door and the attic chamber.

The smelting industry is so busily engaged in burning off its sulphur and allowing it to escape into the atmosphere, keeping a wary eye on agriculturists and politicians the while, that it is easy to overlook the annual return from the sulphur which is being utilized. The value of the sulphur production of the United States last year has been estimated by Mr. W. C. Phalen, of the United States Geological Survey, at $5,500,000. The chief difficulty about sulphur is that it occurs abundantly in places where nobody wants it, and is generally absent from those places where it is required. Since it commands only a comparatively low price, the production of sulphur-bearing material involves business considerations rather than mining technology. Thus, for example, pyrite is imported from Spain to points on the Atlantic seaboard, since the railway freight in this country, with additional handling charges, makes the domestic pyrite cost more in the vicinity of the principal ports than imported material. Sulphur from Sicily used to be imported into the United States in considerable quantities, but of recent years the Louisiana sulphur has been produced and sold so cheaply that Italian imports only amounted to 125 tons of sulphur in 1913, according to Mr. Phalen. Two-thirds of the total sulphur imported comes from Japan, most of it entering at Portland and Hawaii, though some of it enters San Francisco in competition with the copper-bearing pyrite of California. The Hall process, in course of development at Coram, is likely to cause a change in the California situation, but can scarcely affect other points; for freights will not permit the California sulphur to compete with the Louisiana and Japan product at any great distance from its point of origin.

The Louisiana producers are now carrying the war into Africa, and competing with Italian sulphur on its own ground. The principal American company has established a distribution depot in Rotterdam and has chartered steamers for carrying its product. The Sicilian producers are rather dejected, as working costs there go up as the mines go down. Wages go higher, because of the emigration of laborers to America, while the Italian government has restricted the granting of concessions. Some of the deposits have been worked out, and corresponding new discoveries have not been made, so that there is every reason to believe that the Sicilian output will steadily decline. The increasing production of sulphuric acid by the copper smelters is also a factor in the sulphur situation, though probably not a disturbing one; for the smelters are commonly so situated that they cannot compete to advantage with the present makers of acid on account of freight rates. The smelters will, in many instances, have to create a market for their acid, and, since its output of sulphuric acid is often called the index of a country's civilization, progress will thus be made.

GENERAL VIEW OF THE PROPERTY OF THE PORCUPINE

Continuous Decantation at the Porcupine Crown Mines

By MAURICE SUMMERHAYES

The Porcupine Crown Mines is situated on the T. & N. O. Ry., 250 miles from North Bay in the Porcupine mining district, Ontario, Canada, and one-half mile from the town of Timmins. In February, 1913, a small amalgamating mill was built and put into commission primarily for the purpose of testing the mine sampling and also for producing revenue.

The small mill was operated until November 15 of the same year during which time experiments made (both in the laboratory with cyanide tests and the mill on a larger working scale) indicated that the continuous decantation process would be the most economical. This was erected and running by November 15 without interfering in any way with the existing mill, which was made a unit of the new one, the amalgamating plates during the erection of the larger mill being placed in a temporary building which was later removed.

The factors determining the choice of the process were: (1) short time factor for solution of gold; (2) low solution strength required (1.25 lb.); (3) rapid settlement of pulp; (4) low costs of installation and operation (5) small quantity of water required.

The ore is a hard quartz containing approximately 1% of iron pyrite. The grade of mill-run varies from $15 to $30 per ton. Some of the gold is coarse, but generally it is fine and freely disseminated in the quartz gangue, often associated with the pyrite. With the ore proper from 10 to 20% of country rock is sent to the mill.

Crushing and Elevating

The ore is delivered in cars from the shaft house to the mill, where it is weighed and dumped upon a grizzly spaced 1½-in. The oversize falls into an ore-poeket of 60 tons capacity and feeds a No. 3 Chalmers & Williams bronze ball gyratory crusher set at 1½-in. The discharge from the crusher joins the undersize from the grizzly and feeds a vertical belt elevator carrying 120 buckets 9 by 9 in. traveling 225 ft. per minute; this delivers the ore to a short conveyor belt 16 in. wide traveling 200 ft. per minute, which distributes the ore in the bin equally to each battery of ten stamps. The ore bin has a capacity of 265 tons.

The ore is fed to twenty 1050-lb. gravity stamps by standard Challenge feeders. The stamps drop 102 times per minute. The height of drop is 7½ in. and height of discharge 4 in. A stamp duty is obtained of 8.8 tons for the 2½-mesh screens. The battery posts are 12 by 26 in. for the side posts and 20 by 26 in. for the king posts. The top girt for the 20 stamps is framed in one piece giving the 20 stamp structure considerable extra support. Fairlie belt tighteners are used. The mortars are standard narrow type for quick discharge and coarse crushing.

Two and one-half and 6-mesh screens are used on the batteries and varied to suit the mill requirements. The 2½-mesh has openings 0.25 in., and the 6-mesh has openings 0.111 inch.

Classifier and Tube-Mill Closed Circuit

The stamps discharge to two Dorr classifiers, a duplex in circuit with a 5 by 16-ft. tube-mill and a simplex in circuit with the 4 by 20-ft. tube-mill. The 5 by 16-ft. makes 29 r.p.m. and the 4 by 20-ft. 31 r.p.m. The elevation of the classifiers is such that the discharge from the tube-mills will flow by gravity back to the classifiers. In the case of the 5 by 16-ft. tube-mill, this was accomplished by adding 4 ft. to the standard length of classifier, the oversize being fed to the scoop with a

CROWN MINES COMPANY, LIMITED.

solution jet regulated to give 38% moisture. With the 4 by 20-ft. tube-mill the desired result was obtained by increasing the radius of the scoop, the one used having a radius of 52 inches.

Twenty-four feet above the tube-mill floor are placed two amalgamating plates, 9 by 5 ft., receiving the slime discharged from the tube-mills, which is elevated by a triplex plunger pump and suitably diluted. The slope of the plates is 1½ in. per foot. The plunger pump has ball valves, the seats of which in time wear elliptical in shape, necessitating the use of a small amount of air to assist the pump, and later the valve seats must be taken out and reseated.

The plates have now been in use six months without material damage. The amalgam forms on the plates as a hard skin, and is removed with a scraper, care being taken not to get down to the copper. It is impossible to keep the plates soft and in good condition for catching fine gold, as practised in modern amalgamating mills, and this is not attempted. It does, however, pick up the heavy coarse gold, for which purpose only it is required. About 30% of the total recovery is made from these plates.

Cyaniding

The cyanide plant essentially consists of five 30 by 12-ft. Dorr thickeners, working in series, with an agitator, 16 by 16 ft., between thickeners No. 1 and No. 2, together with the various pumping and precipitating apparatus. The pulp is delivered to a No. 1 thickener at a ratio of 5.25 tons solution to 1 ton solids. The overflow from this tank is the 'pregnant solution.' All of this solution is not necessarily precipitated. If the overflow is of lower grade than required, a portion is allowed to by-pass to the pump returning the solution from No. 2 thickener to the battery storage, which is allowed to build up in value to a limited amount (see tabulation following).

The underflow or thickened pulp is directly connected by 4-in. piping to the suction end of two 4-in. diaphram pumps. These are set 3½ ft. above the level of the solution in the tank. These pumps will handle pulp containing as low as 25% moisture over short periods of time. Each pump has a sufficient capacity to handle the maximum output of the mill, thus leaving one pump in reserve. There are two speeds and three lengths of stroke to vary the volume pumped, giving ample variation to accommodate the mill tonnage.

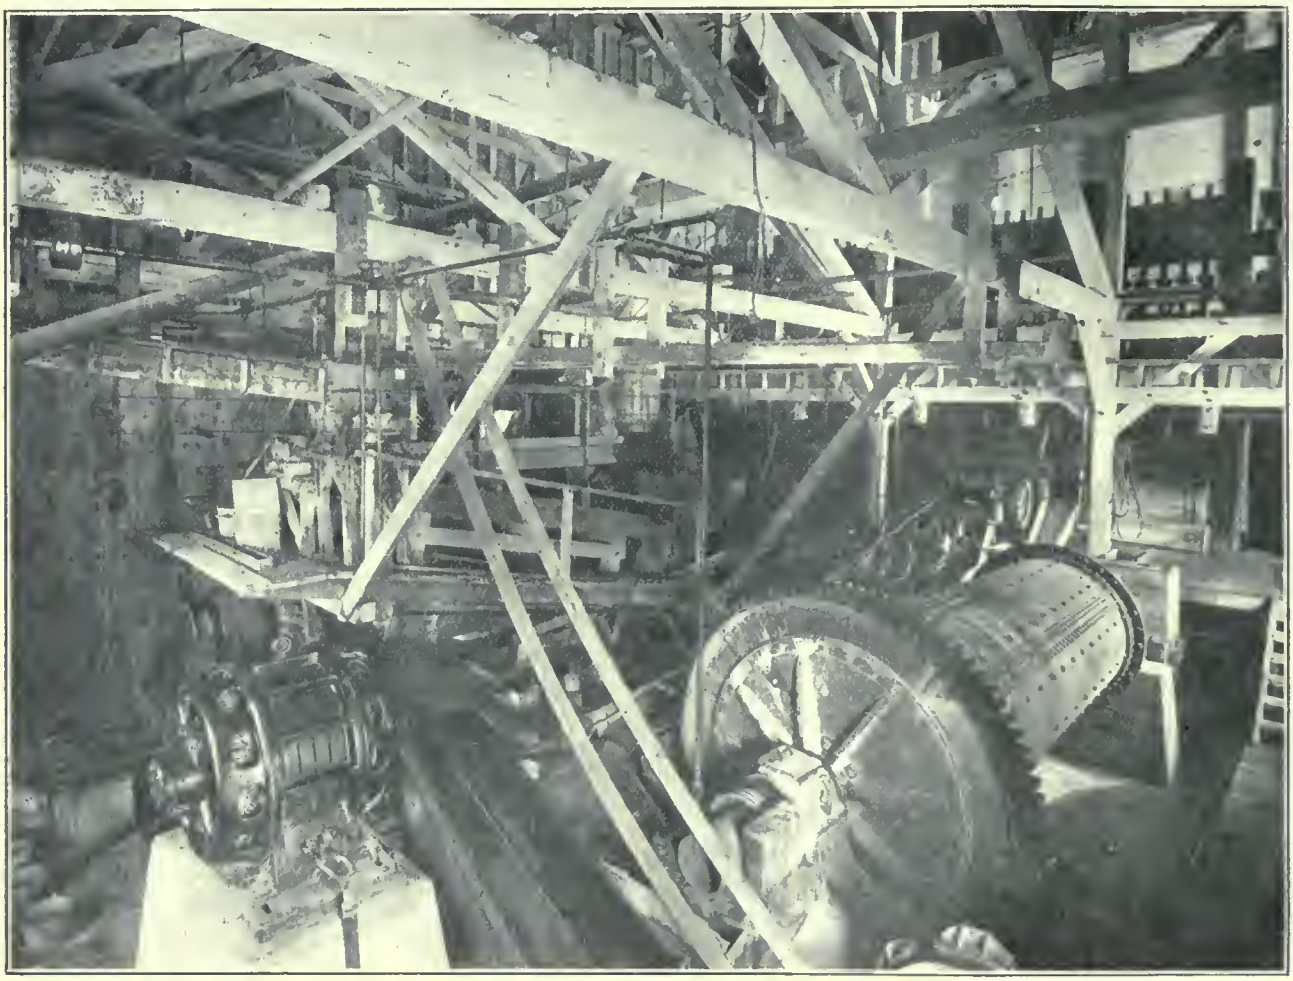
The thick pulp (35% moisture) from No. 1 flows from the diaphram pump by gravity to the agitator. Here the moisture is raised by adding barren solution until the same has reached 60%. One-third of the cyanide is added at this point, the balance at the tube-mill feed. The pulp is discharged from the agitator continuously to thickener No. 2. Then from this point to thickeners No. 3 and No. 4 the decantation is continuous, each tank having a 2-ft. elevation above the next preceding, giving the overflows a gravity flow from No. 5 to No. 2.

The barren solution from the precipitating presses is delivered to No. 4, a small portion going to the agitator. Water only is added to No. 5 equal in amount to the solution leaving with the thick pulp as tailing, thus maintaining a constant volume in the circuit. No. 5 is discharged through a spigot, with an average moisture content of 30% only. The diaphram pumps in each case raise the thick pulp at 35% moisture from the various tanks as already described for No. 1. The solution overflows pass by gravity from No. 5 to No. 2, while the pulp flows in the opposite direction from No. 2 to No. 5. The value of the barren solution from the precipitating presses varies from 1 to 3c. per ton solution. The average assay values of the pulp and solutions in the various tanks during the months of March and April are shown in the tables.

Precipitation

Zinc dust is used as the precipitant and is fed to the suction of an Aldrich triplex pump by a Merrill zinc-

dust feeder. The pump raises the emulsified dust and solution to two 52-in. Merrill precipitating presses. These presses are used alternately for periods of 15 days, when regular clean-ups are made. By this system all delays are obviated and a press is in reserve. One-sixth of a pound of zinc dust per ton of solution has been found sufficient. The barren solution carrying 1 to 3c. per ton flows by gravity to No. 4 thickener and the agitator. The grade of precipitate obtained was $27.50 per pound from pregnant solution averaging $2.87 per ton.



A CORNER OF THE MILL, SHOWING STAMPS AND TUBE-MILLS.

Refining

The process in brief consists in acid treating the precipitate with sulphuric acid, filtering, washing, drying, fluxing, and briquetting the resultant material. This is smelted in a Rockwell furnace.

For acid treating a wooden lead-lined tank, 4 by 6 ft., fitted with a mechanical stirrer is used. The ratio of acid to water is aimed to be kept at 1 to 5, the amount of acid required is three-quarters to one times the weight of dry precipitate treated. The time allotted to acid treating is 6 to 8 hours. The sludge from the acid tank is run into a Perrin press and the strong filtrate of $ZnSO_4$, etc., allowed to run into a wooden tank to settle until the next clean-up. The material in the press is subject to a thorough washing with hot water, which is run to waste. The time for filtering and washing is about 12 hours.

After thoroughly draining and partly drying, the treated precipitate is dropped into a 6 by 11-ft. steam dryer and the moisture reduced to about 10%. The precipitate is mixed with the required amount of flux and briquetted in a Grath Little Giant brick press. Drying, fluxing, and briquetting take about 15 hours. The briquetting machine is made by the Illinois Construction Co. and will handle, when operated at maximum capacity, 960 lb. per hour of mixed precipitate and flux.

The briquettes are charged to a double chambered No. 2 Rockwell furnace using crude oil as fuel. About 8 hours are allowed for the charge to melt down before pouring. The resulting bullion averages about 750 fine in gold and 90 in silver or 840 in precious metals. The slag carries $400 to $500 per ton. Some matte is produced which retains a small amount of gold and silver.

The following are the acid and fluxes used per 100 lb. precipitate:

	Pounds.
H_2SO_4	75 to 100
After acid treatment:	
Borax glass	11.5
Soda	5.7
Silica	3.0

ITEMIZED COST PER FINE OUNCE OF BULLION PRODUCED
AMOUNT PER MONTH

	Cost.	Cost per fine oz.
H_2SO_4, 1260 lb. at $0.125	$ 15.75	$0.0038
Borax glass, 270 lb. at $0.12	32.40	0.0078

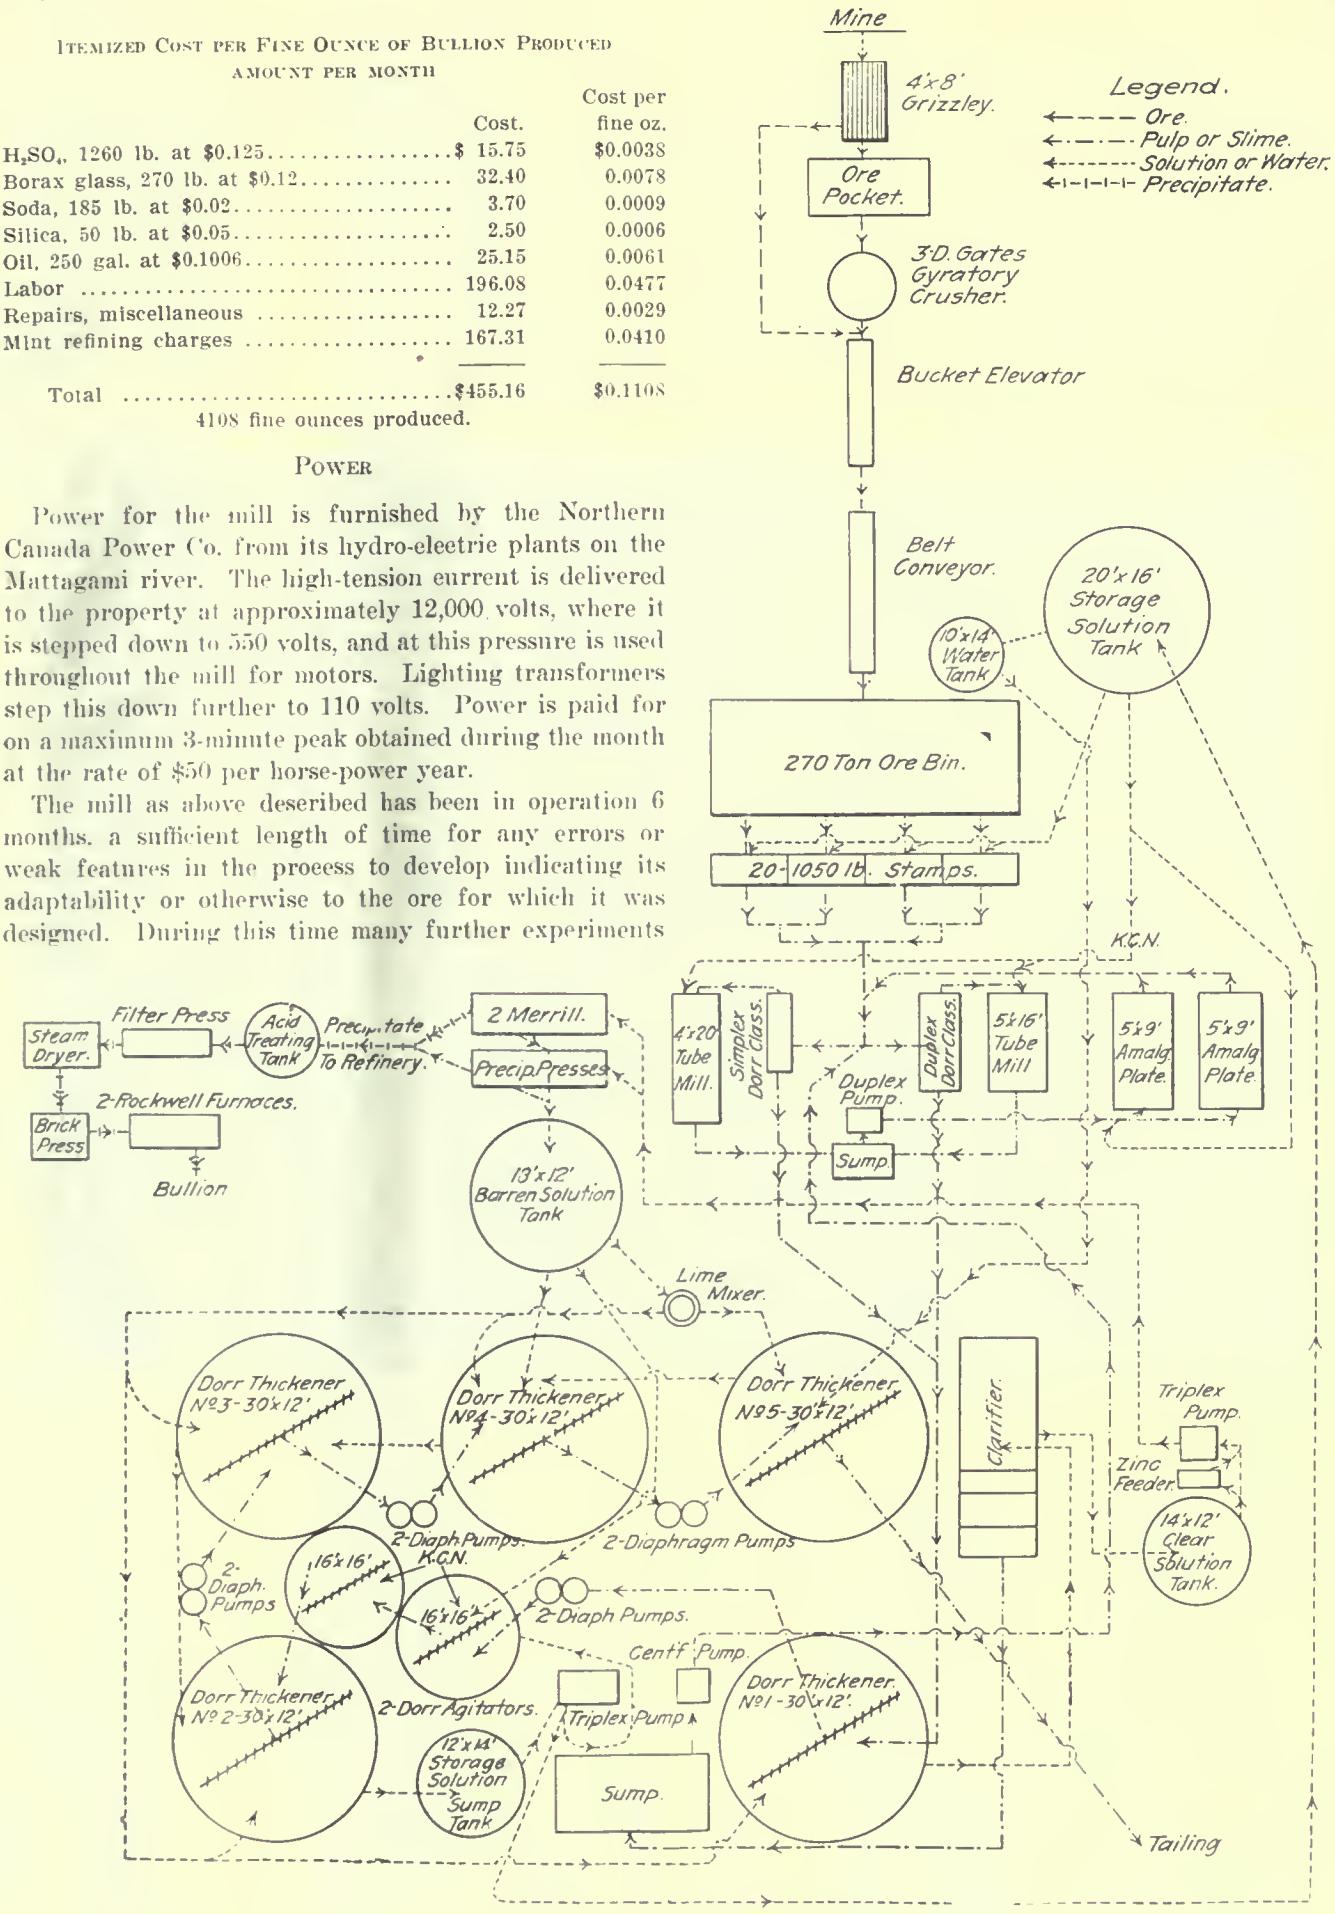
Labor	196.08	0.0477
Repairs, miscellaneous	12.27	0.0029
Mint refining charges	167.31	0.0410
Total	$455.16	$0.1108

4108 fine ounces produced.

POWER

Power for the mill is furnished by the Northern Canada Power Co. from its hydro-electric plants on the Mattagami river. The high-tension current is delivered to the property at approximately 12,000 volts, where it is stepped down to 550 volts, and at this pressure is used throughout the mill for motors. Lighting transformers step this down further to 110 volts. Power is paid for on a maximum 3-minute peak obtained during the month at the rate of $50 per horse-power year.

The mill as above described has been in operation 6 months, a sufficient length of time for any errors or weak features in the process to develop indicating its adaptability or otherwise to the ore for which it was designed. During this time many further experiments



FLOW-SHEET OF PORCUPINE CROWN MILL.

have been made, more especially toward making a more complete extraction without further grinding. As may be seen by a study of the attached assay averages, a further benefit may be obtained by increasing the time for agitation, some metal continuing to be dissolved in the thickeners following the agitator. In this connection it may be stated that a second agitator is now in process of erection. Re-cyaniding the washed tailing pulp with the working solution for 12 hours indicates that not more than about 3c. additional can be expected to be recovered without finer grinding.

of March and April. These are the labor, stores, and power costs only, and do not include proportion of assaying, administration, depreciation, etc., which are normal for a property of this size, our total operating costs for the first quarter of 1914 being $6.75, including all overhead charges.

MISCELLANEOUS DATA

	Per ton milled, lb.	Unit cost per lb.
Consumption of KCN	0.74	$0.160
Consumption of Zn	0.98	0.065
Consumption of CaO	3.50	0.065

INTERIOR OF CYANIDE PLANT OF PORCUPINE CROWN MILL.

There has been milled and cyanided 18,460 tons of ore with the plant described. The extraction has been between 96 and 97. The loss in dissolved metal content in the tailing for March and April was as follows:

	March.	April.
Value of solution per ton	$0.120	$0.100
Value of solution loss per ton of ore milled	0.052	0.043

The above result compares most favorably with any class of filter which might be used on a pulp such as that here treated. The pulp as discharged from No. 5 thickener, containing an average moisture content of only 30%, is in an ideal condition for sampling, and while this has been done by hand up to the present time, an automatic sampler will be installed in the near future.

Attached hereto are the milling costs for the months

arbitrary term used for want of a better. Any standard method of computation would have given a similar comparison.

In the description of the method adopted it is stated that the sand tested must be obtained from wet-crushed samples. This principle can be safely deviated from at times, and if the sample to be tested is put through and through a sample crusher until the required weight of −20 +40-mesh sand is obtained, the result will be accurate. The object is to keep the physical characteristics of the sand always the same. Particles of sand derived from the wet crushing of rocks, and those derived from dry crushing in rock-breakers are always angular, but the particles derived from crushing rock in ball-mills or disc pulverizers are rounded. Naturally, the grinding result on a sample of sand will vary greatly, according as to whether the sand particles are round or angular; and this is necessary to prepare the sand by either of the processes above described. The capacity of tube-mills varies a great deal on different ores, and only experiment will indicate the work that will be performed in any given case.

Tube-Mill Practice and the Hardness of Ores

By W. B. BLYTH

*A simple and accurate method for comparing the hardness of ore sand, judged from a tube-milling standpoint, has resulted from experiments which I have conducted. The principle of crushing in a tube-mill is quite different from that employed in the grinding-pan or the stamp-mill, and what might be considered as excellent crushing material for one machine may prove quite unsuitable for another. This is illustrated by the fact that the most easily ground sand shown in the subjoined table is derived from an ore which in battery parlance is the 'toughest' in the series. Institute of Mining and Metallurgy screens are used because they are the only screens available whose aperture diameter can be guaranteed for a given mesh.

Stadler's† excellent method for computing grinding efficiencies is used to illustrate the respective hardness of the ores tested, but the regrind factor is only an

In designing new plants, the duty of a grinding machine causes the designing engineer a lot of anxiety, as the expected value of the tailing is often strictly proportionate to the fineness to which the ore is ground. At present, the duty on an untested ore can only be guessed from its appearance, which is often similar. A standard preliminary small-scale test from which the capacity of a tube-mill can be accurately estimated would be of value, and the suggested scheme endeavors to supply that want. The attached table of hardness gives the tabulated results of testing sand from 15 mines, and also that derived from crushing an average sample of Danish flints. Unfortunately, it is quite impossible to get correct tube-mill crushing data in each case. I do not have sufficient faith in any method yet propounded for comparing grinding efficiencies to

*Abstract from *Monthly Journal* of the Chamber of Mines of Western Australia.

†*Trans.* I. M. M. XIX., p. 471.

attempt a comparison from the grinding results of tube-mills working under different conditions. Successful comparison can only be attempted when the tube-mills are working under similar conditions with regard to speed, pebble load, grade and tonnage of feed, etc. In only two cases in the subjoined table has it been possible accurately to compare the work done by similar sized tube-mills in the respective plants. In the case of No. 5 mine, whose sand has a regrind factor of 354.5, a tube-mill has a 30% greater capacity than on the sand from No. 11 mine with a regrind factor of 266.3.

Necessity of Having a Standard

Tests on tube-mills working under different conditions on other mines indicate that this ratio will remain about the same, but these tests cannot be accepted as reliable. An elaborated table of this nature would allow operators, working in different parts of the world, accurately to compare grinding efficiencies under similar conditions. Some standard should be established, and this is introduced as a test which can be made by any operator who can secure a set of I. M. M. screens and a 5-gal. glazed earthenware barrel. A study of technical literature dealing with grinding capacities and grinding efficiencies illustrates the fallacy of generalization. It is quite useless comparing capacities and efficiencies of grinding machines unless the ores operated on can be accurately compared.

to 2 in. diameter, and 16 lb. of water, is introduced into a 5-gal. glazed earthenware barrel and ground for 90 minutes at 60 r.p.m. A sample of the ground product is then taken, dried, and graded with a mechanical grader 40, 60, 100, and 150-mesh I. M. M. screens. The value of the grading in energy units is then calculated by Stadler's method, and this amount, minus the original value in energy units, represents the regrinding factor in the table.

Example

	Feed			Tailing		
Screen	Mean factor, Stadler	Percentage ..	Energy units.	Percentage ..	Mean factor..	Energy units.
+ 40	17.5	×100	=1750	16.8	×17.5	=294.0
+ 60	....	....	....	29.2	×20.0	=584.0
+100	....	....	....	16.4	×22.0	=360.8
+150	....	....	....	6.6	×24.0	=158.4
—150	....	....	....	31.0	×26.5	=821.5
Total						2218.7

Total energy units, tailing, =2218.7. Total energy units, feed =1750. Difference, 468.7 = regrinding factor.

A table of hardness based on grinding capacity of tube-mills run under the same conditions, with regrind-

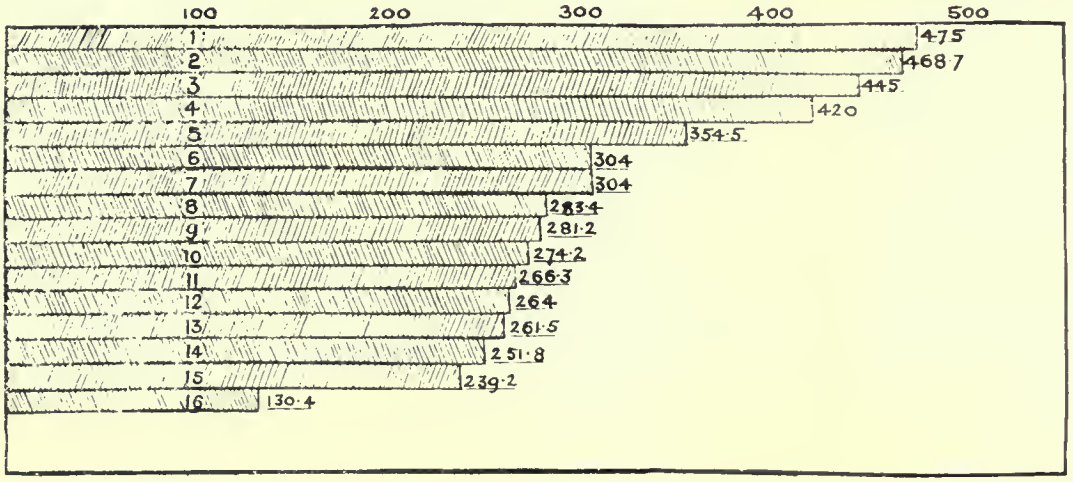

TABLE OF HARDNESS, BASED ON GRINDING CAPACITY OF TUBE-MILLS RUN UNDER THE SAME CONDITIONS. REGRINDING FACTORS IN TERMS OF ENERGY UNITS. THE HIGHER THE REGRINDING FACTOR, THE GREATER THE CAPACITY OF THE TUBE-MILL. REFERENCE TO NUMBERS:

1. Accumulated sand from crushing No. 2 ore.
2. Quartz and schist in highly-sheared dolerite.
3. Sand feed to tube-mills (Broken Hill).
4. Sand feed to grinding pans (Broken Hill).
5. Sulpho-telluride ore (Kalgoorlie).
6. Return raff screen to rolls (Queensland copper ore).
7. Queensland sulphide copper ore.
8. Blue quartz and greenstone (Murchison, W. A.).
9. Concentrated ironstone sand (East Murchison, W. A.).
10. Concentrated jasper sand (Murchison, W. A.).
11. Concentrated ironstone sand (Murchison, W. A.).
12. Queensland sulphide copper ore.
13. Concentrated ironstone sand and garnets (Yilgarn, W.A.).
14. Clean white brittle quartz (Kalgoorlie).
15. Concentrated jasper sand (Murchison, W. A.).
16. Danish flints (tube-mill pebbles).

The method of computing hardness is as follows: A sample of ore to be tested (wet crushed) is graded (I. M. M. screens) until 8 lb. of −20 +40 sand is obtained. A charge consisting of 8 lb. of sand, 8 lb. of flint, 1

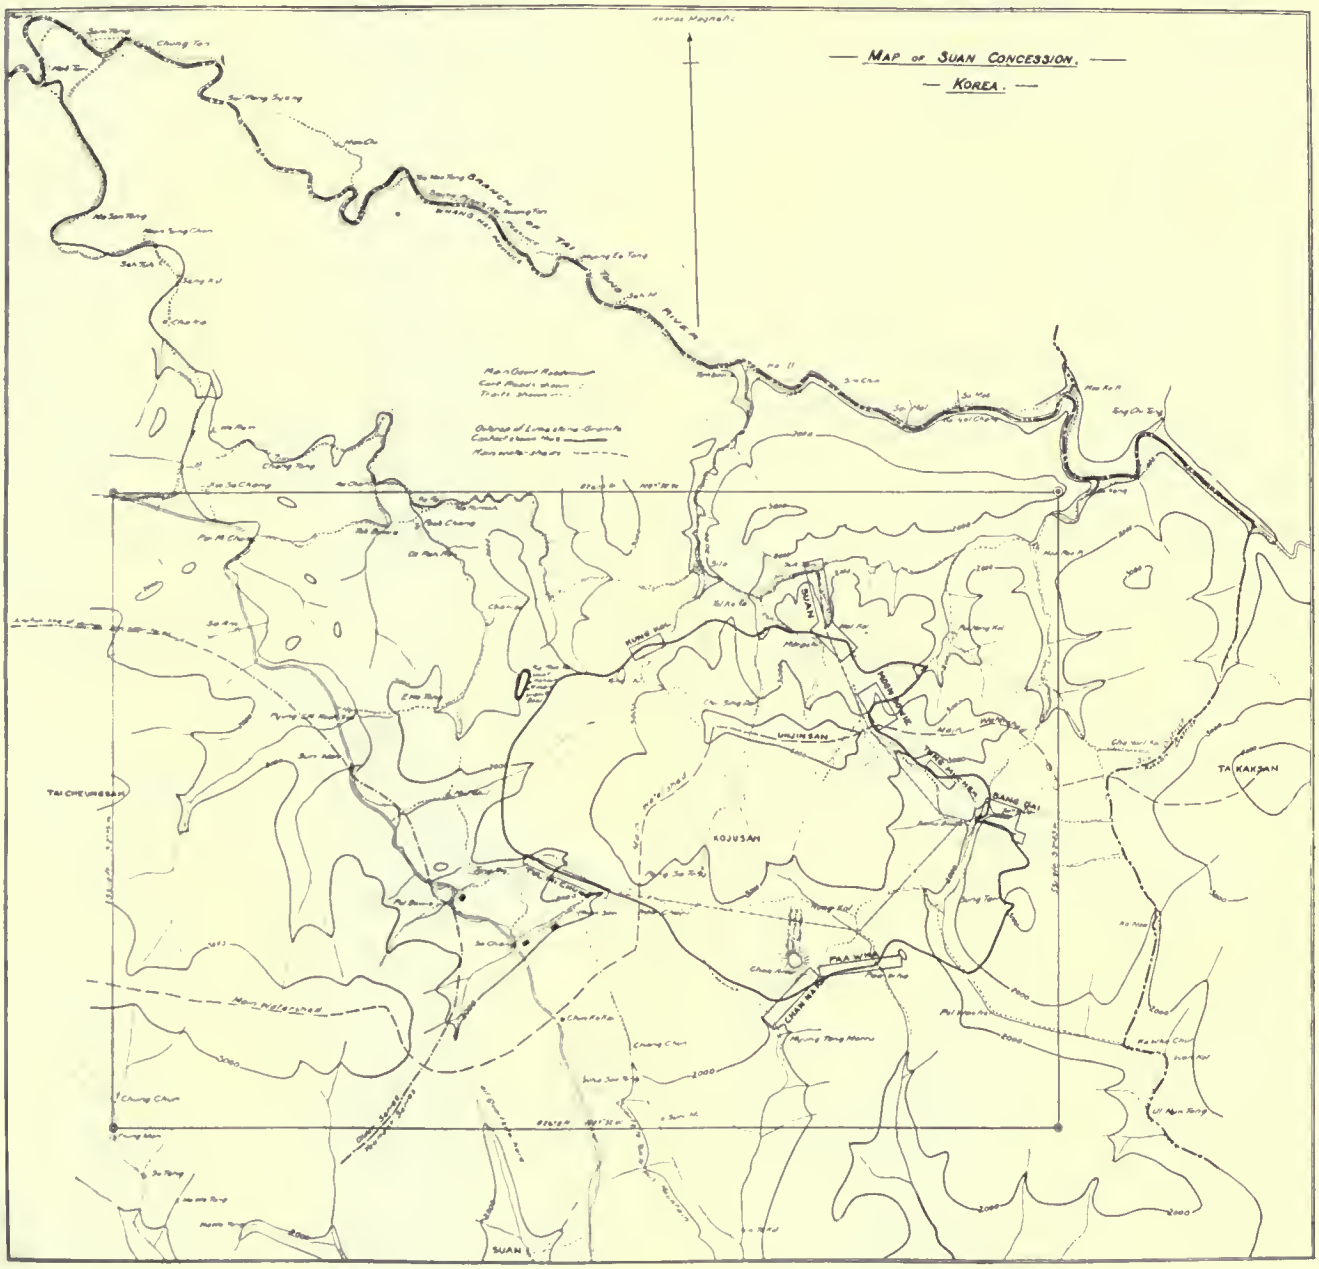
ing factors in terms of energy units, is shown in the diagram above.

The higher the regrinding factor the greater will be the capacity of the tube-mill.

Geological Report on the Collbran Contact Within the Suan Mining Concession, Korea

By D. F. HIGGINS

*The general location of the Suan mining district, Korea, is in central Korea, about 55 miles east-southeast of the city of Pyeng Yang, Korea. The Suan concession covers an area forty by sixty Korean *li*, or an area of about two hundred and sixty square miles. The area mapped in detail in the present survey is in the shape of an elliptical ring, shown by the heavy line on the map, averaging three-fourths of a mile wide and about twenty-five miles in circumference.



The general geologic features of the district mapped consist of a series of sedimentary formations intruded by a granite batholith. This granite in coming up through the outer part of the earth has uplifted and pushed aside the overlying and surrounding rocks with tremendous force. Erosion has bared the mass, showing a rim of upturned edges of the sedimentary rocks around the granite. In the immediate vicinity of the granite, the sediments have been changed — metamorphosed — to schists, marbles, and other metamorphic aggregates.

*Reprinted by permission from geological report made for the Suan Mining Company.

The granite core forms the highest part of the concession, and hence the drainage lines all go outward roughly like the spokes of a wheel. Where the streams cross the contact between the granite and the sedimentary rocks, if there is gold present at the contact, they carry the metal for greater or less distances down from the contact over the outer rocks whose upturned edges often form excellent natural riffles for catching the gold. The principal streams in the district are the Nam Tai Tong Kang, which flows westward along and near the north edge of the concession, the stream which flows northward from near Tul Mi Chung through Pai Mi Chang, about a third of the way from the west side of the concession, and the stream which flows eastward from Suktari to Oo Kang, just inside of the north edge of the concession.

Extent of the Intrusion

The general shape of the main intrusion is an ellipse, with its long axis northwest and southeast, about eight miles long, and the short axis about five miles long. The sides or contact of the main granite in general dip away from the centre of the mass. The angle of dip varies from about 30° to vertical. At no place have I seen a dip of the contact toward the granite, though a local bulge might cause such a condition to arise in some particular spot. The separate areas of granite southeast of Hol Kol are not separate intrusions. The steep granite hill back of the outcrop of the ledge at Hol Kol is almost a similar separate outcrop. A cross-section through these areas would look as shown in Fig. 1. Erosion on the east side of the ridge has reached the granite before the sediments on the top of the ridge have been taken away. More in particular, the contact at Hol Kol is as shown in Fig. 2, where the dotted line indicates the continuation of the contact in its approximate position before erosion. I show this in detail here so that it may be clear that the conformation (which, it must be remembered, is only the horizontal orthographic projection of the intersection of the surface of the contact and the topographic surface) of the contact at Hol Kol does not indicate that a sharp bend or any bend at all may be expected to the south in the east workings, but the contrary.

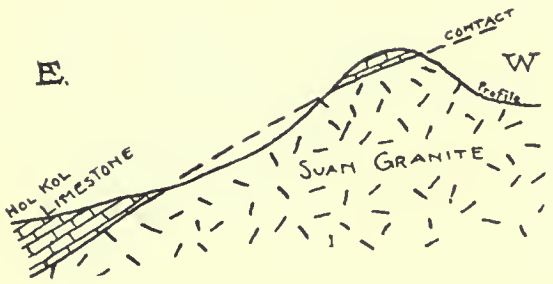


Fig. 1.

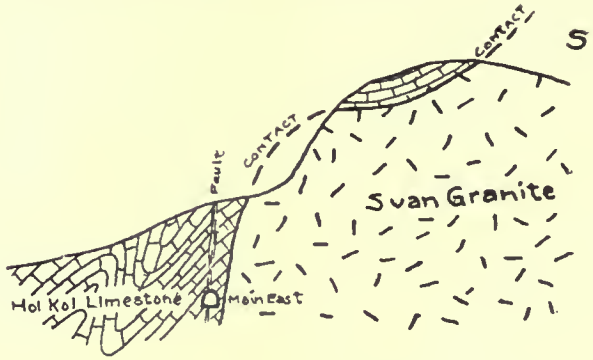

Fig. 2.

Near Nam Nol (and one at Tong Am) there were noted a few quartz porphyry dikes, very light in color and very much fractured into splintery and angular blocks. They have no significance in relation to the mineralization of the district. They may be connected with the Song Hyun granite.

The rocks of the region as a whole, with few exceptions, are doubtless Paleozoic in age. I would make a guess that the Suan slates and the Hol Kol limestone approximate the Carboniferous, and that the quartzite at Tol Ko Kai marks an unconformity between them and lower rocks. The quartzite at Tul Mi Chung may be a separate quartzite, but assuming that it is the same one, it may be assumed for present purposes to mark an unconformity between the Suan slates and the Hol Kol limestone on the one hand, and the Tul Mi Chung and Tong Am limestones on the other.

The fact of the intrusion causes the general structure of the surrounding sediments to be a quaquaversal one in general; that is, the sediments all dip away from the granite, or outwardly. From about Nam Nol to Tul Mi Chung there is a very important exception to this rule, however, for the sediments dip toward the granite. This anomalous condition has been brought about by the great opposition to the Unjinsan uplift offered by the Siroo Pong San massif in the western part of the concession, which was also very likely being uplifted at the same time. The contact along this place is about vertical, but the slates dipping toward the granite have probably had their east edges resorbed by the granite.

Regarding contact metamorphism, it may be said that there is evidence that there was recrystallization of the minerals and rearrangement of the elements both with and without the help of materials from the granite magma. The metamorphism is divided into two very distinct stages. In the first were formed principally silicates, and in the second were formed principally sulphides and the metallic gold-silver alloy.

The Suan Orebodies

At the Suan mine at Hol Kol there are two distinct types of ore in two distinct groups of orebodies. I shall call these the western and the eastern groups. The western group takes in the locally known 'west-

ern orebody' and the eastern group takes in the locally known 'central orebody' and the 'eastern orebody' with both its 'north split' and its 'south split.'

The western group is formed of tabular or lenticular bodies with their surface of greatest extension in the great fault zone which extends along the west side of the Hol Kol valley. The last movement on this fault has been nearly in the dip of the fault. The eastern group consists of far more irregular bodies on a series of interlocking fault zones which all together make up one large zone running about parallel to the contact and at about right angles to the west fault. The average movement in this zone was last down to the south at about 30°, probably a settling of the granite in cooling, and the zone as a whole dips 60 to 80° toward the contact in the upper levels, but seems to be about vertical in the lower levels. The western zone dips 55 to 60° to the south. The western zone continues out into the granite, while the eastern one runs at about parallel to the contact.

The distinctive minerals of the western group are tetrahedrite and dolomite in addition to the other ore and gangue minerals. Sphalerite and galena may also belong in this category. Tetrahedrite and dolomite are never found in the eastern group.

It is clear, then, that the two ores have an entirely separate origin. The western ore was deposited from gold-silver-copper-iron-zinc-antimony-bismuth-magnesium bearing solutions working laterally along the fault zone from the granite into the already somewhat altered limestone. The calcite in the limestone was the mineral most easily ousted by the newcomers. Bismuthinite is less than in the eastern group. Impregnation into the walls did not extend a very great way from the principal fault surface.

In the eastern group, gold-silver-copper-iron-bismuth solutions working upward from some source in the granite below flowed along the complicated channels of the fault zone. As in the eastern ore the calcite was most easily replaced, but diopside and phlogopite were also replaced. The presence of pyrrhotite as an important sulphide in the main east north stope ore must be emphasized here, as it has not been recognized heretofore.

The Gangue Minerals

The principal gangue minerals of the western group are calcite, dolomite, quartz, diopside, phlogopite, and a little garnet. The principal gangue minerals of the eastern group are diopside, calcite, garnet, phlogopite, an asbestos (probably a fibrous amphibole), tremolite (?), wollastonite (?), and a little quartz.

The eastern group is doubtless associated in origin with the miarolitic Hol Kol granite, and the channels deep down in the earth along which the solutions which carried the metals of the eastern group arose, are undoubtedly connected with the 'pipe' of the Hol Kol granite, which is itself a phase of the magma given off after cooling had commenced and after the mass of the batholith as a whole had become stationary.

At Kung Kol there was a deposit of pyrite and other minerals, probably including some magnetite, along the contact. Then the pyrite was partly altered to hematite and the granite to a green soft rock quite unlike the granite in appearance, and part of the limestone was made of a chalky appearance. The present digging may be at a place which is only the bottom of a deposit which has all been eroded away leaving the gold for the most part, of course, in the placers below.

The Tong Am Ore

The ores at Tong Am are different from all of the others in that they do not owe their origin to the Suan granite. They are genetically connected with certain dikes which also occur at the prospect. These dikes have been highly metalliferous. They have both metamorphosed the enclosing limestone and have imparted to it metal-bearing solutions, from which the sulphides have been precipitated. The place is very interesting in its occurrence of molybdenum and of cuprite. The latter mineral was seen nowhere else on the concession, and the former only at Peh Wha. The diorite (?) may be an offshoot from the main granite, but the indications are that it is not only separate, but much older than the granite. Some prospecting should be done at this place up the little valley in which is the main adit, several hundred feet above the adit. At that place copper float may be seen, and there is evidence of one of the dikes nearby to the northwest.

The long directions of the orebodies at Tul Mi Chung seem to be from about parallel to about 30° to the contact, and to be along shear or fault zones. They are more or less closely associated with the 'Weigall granite' and probably bear much the same relation to it that the Hol Kol ores bear to the Hol Kol granite. There is very decisive ocular evidence of pneumatolytic action at Tul Mi Chung; that is, that the circulation and work of magmatic waters has been very active, even altering the 'Weigall granite' to a form scarcely recognizable. There seems to have been considerable secondary concentration, and a critical study of the orebodies might give valuable hints as to the depth to which the deposit may be expected to go. Such a study, to be of great value, should be made before the ore on the upper level is stoped out. At Peh Wha also there has been an unusual activity of the emanations from the granite, but the gold content, at least as far as the prospecting to date indicates, seems to have been a little low.

At Sang Dai there are two large masses of so-called 'garnet-actinolite rock,' which contains also much calcite and considerable amounts of quartz and epidote as important minerals, formed by the metamorphic action of the granite. The ores are associated with certain aplite dikes which are, in part at least, a little later than the granite. The mineralogic and metamorphic changes which have taken place at Sang Dai are very complex and need not be entered into here.

Tong Mu Cheh is of interest on account of the presenee of a good deal of asbestie material, and on account of the occurrenee of considerable amounts of chalcoeite which the Koreans mined in olden times. The diggings at Moonbowie are in a very impure metamorphosed limestone and hornfels with a great deal of garnet roek in the neighborhood. Chemieal activities originating in the granite do not seem to have been very active here. At Myung Tang Morru I saw no signs of mineralization. The opening is rather far from the eontaet. At Chan Na Kol the mineralization present is probably of the same type as that at Peh Wha, and I have already spoken of the area between the two.

Criteria for Guiding Prospecting

From the observations made in the Suan district, the following eriteria for guiding prospeeting have been dedueed. These eriteria are probably not complete, and other persons might suggest alternative or additional ones.

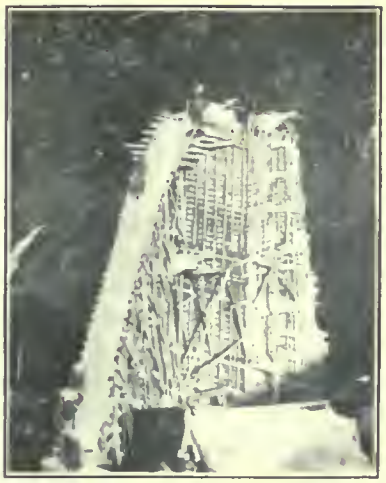
(1) Leached, oxidized, rusty-looking, and copper-stained outcrops (this criterion is, of course, a general one for all districts). (2) Placers either at or below the contaet. (3) Old Korean workings. (4) Contact minerals, sueh as tourmaline, diopside, garnet, ete. (5) Evidences on the surface of faulted or sheared zones in the roek just outside of the eontaet. (6) Limestone contacts are more likely places than sehist contacts with the granite. (7) Especial aetivity of magmatic waters, as shown by the degree of intensity with whieh the metamorphie minerals are localized. (8) Evidenees of differentiation in the magma, as shown by the presence at the eontaet against the granite of small bodies of igneous roek related to the granite.

These eriteria are intended to apply only to deposits along the contact. Especial attention is called to the importanee of the fifth and the eighth ones. The last one is the feature whieh separates Hol Kol and Tul Mi Chung from all the other present openings.

In outline the geologic history of the region seems to have been as follows: First, there was a granite or granite-gneiss land area, now the eentral granite-gneiss of the Siroo Pong San and the Tai Chung San area, on the west of the eoncession. This land was submerged, and on it were deposited various sediments now seen in remnants, as miea sehists, folded in the Siroo Pong San granite-gneiss. The area was uplifted, folded, and eroded. It was again submerged and a series of sediments with a thin quartzite at the base was laid down. The Tul Mi Chung and Tong Am limestones belong to this period. The area again emerged from under the sea, was folded, intruded by certain igneous rocks, eroded, and submerged a third time. Quartzite, the Hol Kol limestone, the Suan slates, and possibly other roeks were deposited. After the following uplift, erosion, and intrusion by the dolerite, and part erosion, there is a great gap in the history whieh would require observations far outside of the region to fill. There was probably another series of sediments laid down which have now entirely disappeared from the eentral part of the earth. It is likely that at the same time there was a doming to the west which is now seen as the Siroo Pong San massif. With the eooling of the Suan granite sundry after aetions took plaee, ineluding the appearance of the Hol Kol granite, Tul Mi Chung quartz-porphyry, ete., to whieh are due the formation of the ore deposits around its border, and the last of which was the rising of the basalt. The settling of the region southeast of the eoncession while lava poured out over it and buried the former topography was the last chapter. Today the processes of erosion are busily at work leveling the mountains for the beginning of another eyele.

General Conclusions

To reeapitulate the origin of the ores, referring, of course, in partieular only to those along the contact with the Suan granite, one must conceive of the granite as being in a molten state or in a liquid state somewhat akin to the molten state, in which a large amount of superheated water may be thought of as aeting as an exeeedingly powerful solvent. An excess of potash and alumina having crystallized out as the orthoelase phenoerysts, the rest of the substanees began to erystallize together with the slowly cooled magma. When the outer shell of the mass was hard it eraeked to relieve the tensile stresses set up in itself by its further eooling, and through these eracks eame parts of the inner uneonsolidated magma, and, more important for our purposes, the water released by the solidifieation of the inner parts of the magma. Much evidence suggests that this water was alkaline in nature and that it bore in solution metallic sulphides sueh as iron, eopper, bismuth, etc., as well as gold and silver in some soluble form. It eontained also fluorine, boron, and silica. It ehanged gradually in composition. The substanees, notably ealeite, in the wall-rock against the granite precipitated the sulphides (and the sulphides precipitated the gold and silver), whieh the water exehanged for the materials of the wall roek and took its new load of non-metallie material away with it (the proeess of metasomatism). Finally erosion bared the whole thing so that man has been able to get at the mineralized plaees, and loeally surface water has worked a seeondary concentration of the sulphides while erosion was in progress. Sueh is the history of the ore deposits of the Suan distriet. The Suan distriet probably offers one of the finest examples of eontaet metamorphie phenomena to be found in the whole world. With study and some good ehemieal analyses. I am certain that some of the mooted problems of the formation of ore deposits and of eontaet phenomena in general would be definitely settled for that distriet at least, and the distriet eould be made a classie one in the annals of geology.



A Concrete Head-Frame

By C. T. JACKSON

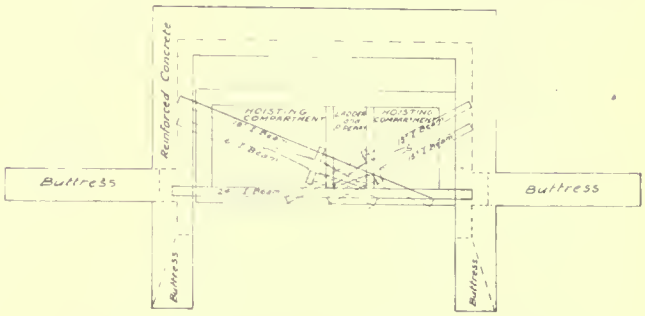
The No. 1. vertical shaft at the Perseverance mine of the Alaska Gastineau Mining Co. has a total depth of 1544 ft. The collar of the shaft has an altitude of 2300 ft. above sea-level. The shaft is intersected by the Alexander cross-cut at a depth of 905 ft., and the main hoist is built on this level in a station cut in the foot-wall. The ropes from the drums pass up a raise and under deflecting sheaves, then up the ladder-way compartment of the shaft and over the main sheave wheels near the top of the reinforced concrete head-frame, and then return to the cages.

Owing to the collar of the shaft being on a hillside

FINISHED HEAD-FRAME AT PERSEVERANCE MINE.

and also at this elevation a very heavy snowfall being experienced during the winter months, a reinforced steel and concrete head-frame was designed, in which the sheave wheels are placed at a sufficient height to provide a safe margin for over-winding.

In building the concrete head-frame all lumber for forms, cement, and sand was hoisted up the shaft and



PLAN OF HEAD-FRAME, SHOWING POSITION OF SHEAVES.

the rock was taken from the hillside nearby and washed before using. A small gasoline mixer was used for mixing the concrete. The mixture was, 1 of cement, 3 of sand, and 5 of rock. The mixer was placed on the hillside near the rock pile at a sufficient elevation so that the concrete from the mixer was wheeled along a scaffold and dumped into the forms and tamped. The reinforcement used consisted of old 12-lb. rails and worn hoisting cable. The walls of the head-frame have a thickness of 2 ft. 6 in. at the base, and taper to 1 ft. at the top.

After the concrete had set a few days the forms were removed at the back, and a dry wall consisting of large rocks was built up to a height of about 25 ft. Loose gravel and rock was then sluiced down and placed at the back of the head-frame to a depth of about 25 ft., giving it a batter from the head-frame to the hillside, so as to take up the heavy snow pressure.

NEW PLANT on the Government Gold Mining Areas Consolidated mine, Johannesburg, during the first quarter of 1914 cost $490,000. A 50-drill Fraser & Chalmers air-compressor was installed, and good progress was made with foundations and buildings of the mill. This is to consist of the following: one hundred 2000-lb. stamps to crush 50,000 tons of ore per month, ten 6 by 16½-ft. tube-mills, amalgamating plates after the tube-mills, three sand-collecting tanks 56 ft. diameter to hold 740 tons each, belt conveyors and Blaisdell distributer to fill eight leaching vats 56 ft. diameter, six 19½ by 70-ft. slime-collecting tanks, nine 15 by 45-ft. air agitators, and a Butters filter plant.

GYPSUM PRODUCTION of the United States in 1913 was 2,599,508 short tons worth $6,774,822, compared with 2,500,757 tons and $6,563,908 in 1912. Gypsum sold crude amounted to 463,136 tons, of which 85% was used for portland cement.

The Mining Law—Proposed Revision

By F. R. INGALSBE

It seems almost self-evident, considering the many articles on the subject which have recently appeared in the mining journals, that there is a basis of fact for some of the criticisms aimed at our federal statutes relating to the locating and patenting of mining claims on the public domain. I believe that the law is good in the main, and in the discussion which follows certain changes are proposed, none of which, however, would conflict seriously with the basic principles upon which our law was written. For instance, I believe that the discovery requirement is basically sound and an annual amount of assessment work is consistent with the proper development and disposal of our public mineral lands, for it is only by development that ground can be classed as mineral or non-mineral. To do away with the discovery requirement would mean either one of two things: the Government would be confronted with the necessity of classifying all its mineral lands and alienating them from all other forms of entry, which would be an immense task, and, on the face of it, impossible; or it would mean that a leasing system must be worked out which would provide for the reversion of such lands to the Government as were shown upon exploration or abandonment to be non-mineral bearing. It seems unlikely that the mining industry of this country would look favorably at the present time upon any leasing system which could be devised as applied to the whole body of metal-bearing mineral lands, and, on the other hand, it scarcely seems probable that the Government will attempt the classification of all its public lands as to mineral character at the present time. Great cost and unsatisfactory results would probably stand in the way. If such a classification were certain of fairly accurate results the cost would probably not be seriously considered, but any field engineer who has spent a few seasons in examining promiscuous undeveloped mineral claims can fully appreciate the difficulties in the way of classifying areas on which 'gophering' has been done, not to mention those where no prospecting at all has been done. The reasons for this depend upon geologic principles which are outside the purpose of this discussion. Those persons who are prone to find fault with a Department for enforcing the mineral laws should not forget that there are thousands of mineral claims in the Western states on which not a stroke of work has been done since the day patent was issued. This condition becomes the more deplorable when we realize that our public mineral land is fast passing into private control, and it is only a matter of a few years when there will be no mineral land to patent.

Admitting that our present system is better than a new one which would entirely overthrow the present law as a whole and the interpretations of the courts for many years past, we will assume that it needs modernizing in some respects, and that Congress should provide means for universal enforcement. I believe the following points are worth consideration in detail:

1. There is considerable ignorance in some localities as to just what our law means.
2. Certain injustices are possible under the present law.
3. Opportunities for fraud under the present law exist.
4. The lode claim is not large enough to provide adequate protection to a valuable mineral discovery, hence the so-called 'protection claims' have come to be a customary means of supplying that protection, although these claims have no legal existence other than that condoned by custom.

Ignorance of the Law Too Common

If any revision of our mining statutes is made, it should be in such clear language that its exact meaning cannot be doubted; and then the Governemnt should undertake a crusade of instruction by posting the laws in all postoffice, land office, and other public buildings in the public land states, and by supplying copies of it at all public offices for free distribution to interested people, without making it necessary for them to write to the proper officials for a copy. Out of the several hundred prospectors and locators whom I have visited I cannot recall one who had a copy of the Federal mining statutes at hand.

I am satisfied that in the past, and to a great extent at the present time, a great deal of the criticism of the present law is based upon ignorance of its exact meaning and interpretation by the courts. The Government has not been careful enough to educate the public. In the course of my own work I have been asked many times by old prospectors and by officials of mining companies just what are the requirements for patenting mineral claims. Probably most of these people knew the approximate wording of the law, but they did not know the interpretation placed upon it by the courts. Some were inclined to emphasize the mineral discovery requirements, thinking it necessary to have pay ore, while others were inclined to emphasize the good faith requirements, believing that properly performed assessment work was sufficient evidence that the prospector believed he had mineral in sight or in reach and that such a condition should pass for a mineral discovery. There is little doubt that in some localities custom had condoned the latter situation before examinations were made by the Government; in fact, in some localities the mineral discovery requirements of the federal statutes were overlooked entirely by locators, and naturally when the Government inaugurated the system of examining claims which came

up for patent there were many disappointed people, a few of whom were attempting to obtain patent to land with no apparent mineral value, but with very apparent value for some other purpose, while others were in absolute good faith but did not know the actual requirements of the law.

Certain Injustices Possible

Under the present law there are certain injustices apparent, the most conspicuous one perhaps being under the placer law, which makes it possible for an association or company of 8 people to locate and hold legally 160 by doing the same amount of assessment work required of a prospector on his 20 acres, which is the maximum area he can locate as one claim. If he wishes to locate 160 acres, he must make 8 locations and do $800 worth of work, whereas if he is dishonest he will locate 160 acres as one claim by making use of 7 dummy locators, thus saving $700 worth of work, the labor of locating 7 claims and the expense of recording them. Such a law encourages crookedness, and what is the reason for such provisions? Why not require $800 worth of work of the 7 locators on the 160 acres? I am unable to answer the query to my own satisfaction. The same principle was not carried out with regard to lode locations.

Another injustice sometimes arises in cases where a poor prospector has a valuable location on which he has done his work honestly. The large company or individual with money overlaps the prospector's location and applies for patent. The prospector is compelled to resort to law for protection. To be sure, the deputy mineral surveyor should exclude the conflict when it is an earlier valid location, but he is not always in possession of the facts and may take the statement of his client, since in such cases he can hardly collect fees for time spent in such investigation. A valid mineral location should be automatically protected by the Government against such encroachments, for it often happens that the ground is lost to the prospector simply because he cannot afford to carry his case into court.

I believe an effective method of protection could be brought about by requiring every mineral location to be examined at the expense of the Government within a reasonable time after location, as to conflicts if any, location work, marking upon the ground, and roughly as to its dimensions and relation to nearby public monuments, accepted surveys, or other fixed landmark. This work would require a competent man in each important public-land mining district who would do the field work and keep complete accessible records of his work. This would also prevent another evil, which has flourished in some localities, that of staking out oversized claims. It probably would not be necessary at this time to examine the claim as to mineral discovery (unless the claim is made larger than at present), but the examiner should be in possession of any facts which tend to prove fraud on the locator's part. Such an examiner would be in a position to report quickly and accurately upon claims which were protested by neighboring locators for lack of discovery or assessment work, either at time of making application for patent or earlier if the necessity should arise. The Government would always be in possession of the facts as to whether the locations were fraudulent or valid and would place itself in a position to protect effectively the poor locator. It would also decrease largely the fraudulent locations and save to both the Government and individuals a great deal of litigation, all of which is a heavy expense and too often creates hard feeling. By thus nipping the trouble in the bud I believe that the Government would do itself and its citizens, and particularly the mining industry, a great service. It would have a tendency to stimulate prospecting by men with the physical and mental equipment for such work. If such a federal office were created it would be a good place to record all mineral locations made in the district, thus supplying the Government with such records.

Protection for Locators

In a few mining localities, where it is in most instances impossible to make a mineral discovery at an expense of $500, some provision should be made to protect a locator while searching for ore. In such districts ore is found only at depth and it is unreasonable to require a mineral discovery at the time a claim is located. I believe such districts should be set aside by the Interior Department and a plan devised for allowing prospectors to make a limited number of locations under adequate protection for a fixed period which would be long enough to allow mineral discovery to be made. In return for such protection the prospector should consent to do a reasonable amount of properly conducted work on each location each year, such work to be done with the view of making a mineral discovery at the earliest time consistent with good work. The Government should have a competent engineer in the district, whose duty it would be to supervise for the Government's interest the locating and developing of these protected claims. As soon as a mineral discovery is made on any claim it should be alienated from the protected area and subject to the general mining laws in force on the public domain at large. At the time the mining laws were made by Congress no provision was made for such a condition, and it seems only proper now that such a condition is known to exist that the Government should make adequate provision to meet the situation.

Under the Act of January 22, 1880, (26 Stat. 61) the locator is allowed the full calendar year next succeeding the one in which the location is made within which to perform first assessment work, that is to say, if a location is made in January 1914, the claimant has until December 31, 1915, a period of two years (Mills *v.* Fletcher, 34 Pac. 637), in which to do assessment work for one year. By relocating the ground every two years a valuable piece of ground can be tied up indefinitely

and put beyond the reach of locators in good faith, or even of the Government itself. This statute is notoriously abused by that class of men who make fraudulent mineral locations on ground valuable for agriculture, water power, townsite, right of way, etc., and thereby make no end of trouble. I believe this law should be stricken from the statute books and another substituted, if necessary, which would make it necessary to perform $100 worth of assessment work not later than one year from the date of location, or in case of failure to do so, automatically proclaim the location legally abandoned. And in case a claim becomes automatically abandoned there should be a period of at least one year between the date of automatic abandonment and the date on which it might be relocated by the same person or company.

The Door Thrown Open to Fraud

It has been possible in the past to locate land valuable for timber, agriculture, water-power, or townsite, as mineral claims, and even to patent such a group without having any indications of valuable mineral in sight, because the Government has not supplied the means of enforcing its laws. It is possible, even now, to do so on public lands outside of the national forests, for only a fraction of such claims are ever examined by Government officers to determine their mineral or non-mineral character. Such examination has been carried on within the forests and the records show that hundreds of claims have been canceled, after a hearing was had, because of lack of compliance with the Federal statutes. It is true that a good proportion of such canceled claims were protection claims but many cases of absolute fraud have been brought to light. A perusal of pages 5 to 10 of the United States forester's report for 1912-13 will leave no doubt as to this fact, and to my mind is a very eloquent argument for the examination of all mineral claims for which patent is asked. As to the protection claims, there is a strong argument in favor of the miner, sufficient in many cases to justify the conclusion that there is a defect in the law as it now stands.

The Size of the Lode Claim

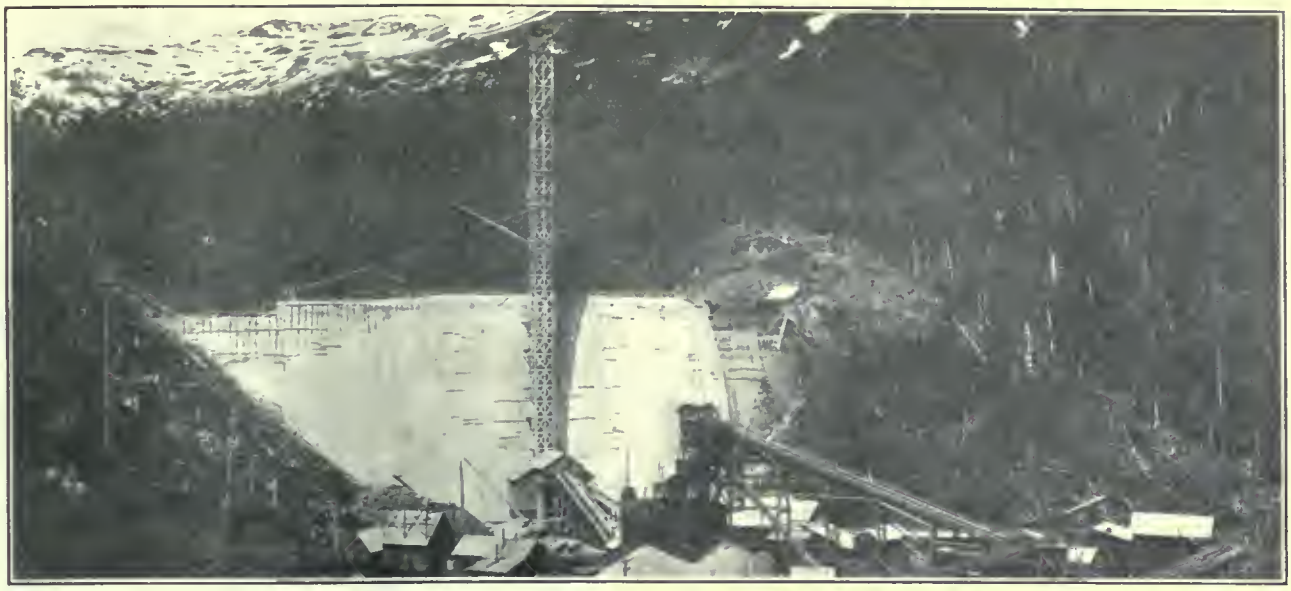
In order to avoid the necessity—for it is often a real necessity—of making these blanket locations around a discovery, I propose the enlargement of the lode claim from 20 acres to say 40, in the form of square or rectangular tracts, laid out by legal subdivision of the public survey. Such a change would make the claim large enough for protection against speculative locators whose policy it is to take advantage of the real discoverer's labor, and at the same time would automatically do away with the necessity of extralateral rights, thus forestalling for the future the greatest cause for litigation the mining industry has had to cope with. This would automatically stop much of the injustice perpetrated by the wealthy mine owner upon the prospector and miner, under the guise of the present apex law. In case the size of the claim is increased it might be wise to require $100 worth of work for each 20 acres, or fraction thereof, in the claim and to enforce the discovery requirements very strictly in order to prevent tying up of large areas of country. I realize that this is touching upon dangerous ground, but it is presented only as a suggested way out of a real difficulty.

In this argument, for which I am personally responsible and act in no manner as a spokesman for any Government bureau, I have proceeded upon the assumption that criticism has very little or no constructive value unless it is backed by suggestions for a cure. In fact I recognize that it is absolutely impossible to make a set of mining laws which will suit every one.

Right here I can do no better than to quote from the 'Twentieth Annual Report' of the Bureau of Mines of Ontario, Vol. XX, Part 1, p. 270, 1911, where mine commissioner S. Price has so aptly expressed the situation when he says, speaking of mining laws in general: "* * * Probably no law upon the subject anywhere has ever had the unanimous approval of those working under it, for individual opinions and points of view differ even more widely than the laws. Poor prospectors and rich capitalists, men with little and those with large experience, those who want to find something to develop and those who desire merely to get something to sell, the miner who wants to work the land for the valuable mineral he expects it to produce and the speculator who desires only to hold it while neighboring development increases its value, can hardly be expected to view matters in the same light or to desire the same kind of a law; nor is the interest of any of them always identical with the paramount interest of the community as a whole to which the property in the first place belongs. * * *"

In the above argument I have had in mind justice to the poor prospector, the interests of the mining industry at large and that of the country as a whole. The difficulties in making and administering mining laws are largely brought about by unscrupulous locators and stock venders who are 'in the game for what there is in it,' and I freely acknowledge that such do not belong to the mining fraternity proper. If everyone were honest there would be very little difficulty under the present law, but human beings are still human and to some extent selfish, all of which requires that the central government should take a strong hand in the administration of its public land laws in the interests of common justice.

It Is a Curious Fact that the United States, with enormous deposits of iron ore, depends on deposits in foreign countries for most of its supply of the metals used as alloys in the manufacture of steel, such as manganese, nickel, chromium, and vanadium, according to the U. S. Geological Survey. The production of ferromanganese, spiegeleisen, and other alloys in 1913 amounted to 226,475 tons, against 128,147 tons in 1912.



DAM ON THE SALMON CREEK POWER DIVISION.

Developments of the Alaska Gold Mines Company

By E. E. HURJA

Probably nowhere in the world has mining on such an immense scale been undertaken by so many companies as in the Juneau (Alaska) district; so therefore a review of the present status of the Alaska Gastineau property, held by the Alaska Gold Mines Co., may be of interest to mining men generally. The Company has three miles of claims along an orebody varying in width from 70 to 400 ft., and carrying from $1.50 to $2 per ton in gold, with a net profit of from 50 to 75 cents per ton because of the large-scale production. The mining work of the Company is conducted from Sheep Creek, four miles south of Juneau, and the work on the power project is on Salmon creek, four miles north of Juneau. The main offices of the Company are at Juneau, with B. L. Thane in charge.

Mine Development

The underground development up to the present time includes the Alexander adit, known as tunnel No. 10, at the Perseverance mine, in Silver Bow basin, which has been extended and is now 5000 ft. long. Crosscuts are being driven from this and from the main adit, known as the Sheep creek tunnel, which connects the Perseverance workings with the millsite overlooking Gastineau channel at the mouth of Sheep creek. A vertical three-compartment shaft, 1544 ft. in depth, connects with the 8 by 10 adit having a length of 9178 ft. The work on the adit was started in November 1912 and was completed April 1, 1914. During the last six months a monthly rate of 600 ft. was maintained. Three shifts were worked on the bonus system in completing the tunnel. Thirty-three feet were made in a single day during November.

An electric tram 1¼ miles long connects the portal of the adit with the coarse-crushing plant on Sheep creek. The present gage of 24 in. is to be changed to 36 in., and the storage-battery locomotives will be replaced with the trolley system. All the mining will

THE OLD PERSEVERANCE MILL.

be conducted through the main adit, and ore hauled to the reduction plant in 300-ton trainloads.

Reduction Plant

The first unit of the reduction plant of the Company probably will be completed by January 1, 1915. The coarse-crushing plant, situated on the hill 700 ft. above the beach, is almost completed. The foundation and

steel framework are completed and the machinery is now being installed. The ore falls into underground storage-bins and is hauled by a bucket line through an underground tunnel, 300 ft. long, to the fine-crushing plant. The concrete foundations for the fine-crushing plant are nearly completed, and the steel for the framework is all on the ground. The sides of the building will be of galvanized iron. After a preliminary sorting, the ore is crushed by Hardinge conical mills, then taken over amalgam tables to the concentrating department. Wilfley tables and Garfield roll mills will prepare the concentrate for the re-treatment plant. Experiments with a view to cyanidation of concentrates are still in progress. The first unit will have a capacity of 6000 tons daily.

Machine-shops, sawmill, six bunk-houses, mess-house, office buildings, and dock have been built on the beach, immediately below the reduction plant, the floor of which is 300 ft. above sea-level.

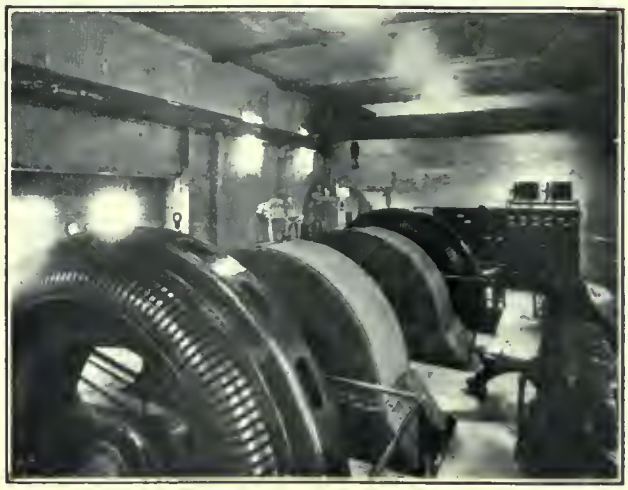
Power

The Salmon creek power project will be completed by July 25, 1914, according to statements of the engineers in charge. The first concrete for the dam, which is of the variable radius arch type, was poured July 25, 1913. The dam will have a height when completed of 177 ft., with a length along the crest of 650 ft., and the thickness at the base will be 47 ft. On June 25, 26 ft. remained to be built. Following the completion of power-plant No. 1, which is on the beach at the mouth of Salmon creek, in 1912, a 4½-mile tramway was built and building erected for work on power-plant No. 2 and the dam. Power-plant No. 1 has one unit of 1500 kw. installed. The second unit will be installed in the spring of 1915. The plant is closed down for repairs at present. Power-plant No. 2, with two generating units of 1500 kw. each, is completed, and is furnishing all the power for present operations of the Company. The beach at Salmon creek is being bulkheaded to protect the buildings and road from tide action. A concrete tail-race will be built.

In order to handle cement and supplies with dispatch, a special dock was built, with a highly practical apron track by which loaded cars of cement can be moved from the barges directly upon the tramway. Barges bearing fifteen 3-ton cars are unloaded and empty cars put on board in 40 minutes. Three hundred and five tons of cement is the record amount handled during a single day. A 2000-ft. cable tramway raises the cars 300 ft. to the steam road leading to the dam-site.

When complete, the dam will impound 20,000 acre-feet of water. Above the dam, in what will be the reservoir area, the quarry, gravel, and washing plants are situated. Belt conveyors carry gravel, sand, and cement to two mixers with a daily capacity of 700 yd. As much as 860 yd. has been poured in 24 hours. The concrete is hoisted in a 2-compartment tower 75 ft. high, shown in the halftone, for distribution. A ditch 3850 ft. long is being built to drain the north slope of the basin below the dam into the reservoir. The construction camp at the dam is roomy, clean, and well drained; shower baths, toilets, and other conveniences are provided.

Computing the width of the ore at 70 ft., the orebody above the main adit is estimated to contain 50,000,000 tons, assuring operation of the mill for many years to come.



INTERIOR OF POWER-PLANT NO 2, ALASKA GASTINEAU COMPANY.

Costs at the Great Fingall Mine

Ore extracted from the Great Fingall mine, Western Australia, is of a free-milling class, which is stamped, concentrated, concentrate roasted and cyanided, sand leached, and slime treated in a vacuum-filter. It was mined down to the No. 18 level, a depth of 2480 ft. on the incline. Costs per ton were as follows:

Ordinary development	$0.91	Leaching sand	$0.22
Special development	0.99	Filtering slime	0.24
Mining:		Ppln. and clean-up	0.08
Breaking ore	$1.25	Disposal of residue	0.18
Filling stopes	0.12	Treating custom ore and concentrate	0.12
Tramming and hoisting	1.52		
Total mining	$2.89	Total treatment	$2.08
Treatment:		Less custom account	0.19
Crushing	$0.15		
Transport	0.04	Net treatment cost	$1.89
Stamping	0.62	Bullion expenses	0.06
Concentrating	0.04	General expenses	0.62
Concentrate treatment	0.07		
Grinding sand	0.32	Grand total	$7.36

Crude Barytes Production of the United States in 1913 was 45,298 tons worth $156,275, an increase of 7820 tons and $2962 compared with the yield in 1912. Most of this mineral is used as a pigment in the manufacture of mixed paints.

Coke Production of New Mexico in 1913 was 467,945 short tons, valued at $1,548,536, an increase of 54,039 tons and $191,590 over 1912. The coke is from the Raton field coal.

DISCUSSION

Readers of the MINING AND SCIENTIFIC PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Workman's Compensation

The Editor:

Sir—While on a recent trip through Sierra and Nevada counties, I noticed that the workman's compensation law is not altogether popular. The general comment is, that it is hard on the small mine owner. One man who is developing a prospect, and who says he can't afford the extra tax, is employing only unmarried men. Another, has leased his mine and mill to the men, giving them a bonus of ten per cent of the net; above wages and supplies. The lease runs only 30 days, being signed over again at the beginning of each month. He says this works very well. The men are more saving with supplies, and the increase in the amount of work done, more than repays the ten per cent. But I doubt if this would evade the law in case of an accident. Being the owner, he is probably just as responsible as the man who lets a contract.

Insurance is a good thing,—for the workman,—and good for the owner, as protection against possible damage suit. But it is not fair that the mine owner should stand the whole expense when the miner is the chief beneficiary. Let the mine owner pay one-third of the tax, and the miner two-thirds. It can be deducted from his monthly paycheck, just as some of the mining companies used to hold out a dollar per month from each check for the services of the doctor.

Value of Dredging Ground

The Editor:

Sir—In Mr. Decoto's article, I can see where he can prove his contention that no part area of a given area of dredging ground is representative of the total area, as regards its value, but it does not seem to me that the correct value per cubic yard of his theoretical plot has been arrived at by his method of computing the same.

I get from his article that the dredging operations are limited, in this theoretical case, by the lines connecting drill-holes No. 1, 3, 18, and 16. This being so, these corner drill-holes, taken individually, would be representative of only ¼ the area of that of an interior drill-hole, say No. 5 or No. 7. Likewise the holes No. 2, 8, 13, 12, 6, and 11 would be representative of only ½ the area represented by holes No. 5 or 7.

The computations, then, to arrive at the correct value of the area bounded by lines connecting drill-holes No. 1, 3, 8, and 6, would be:

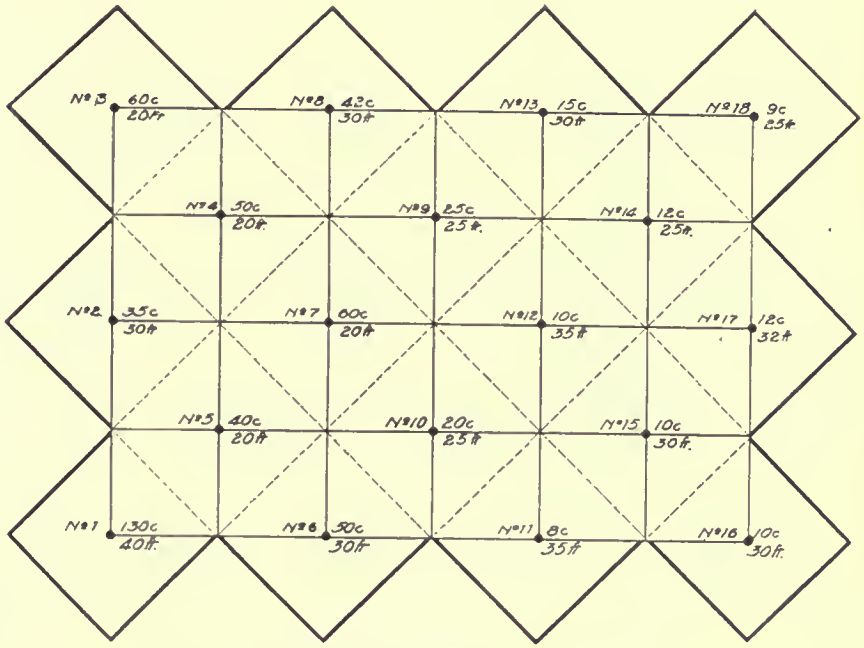

DIAGRAM SHOWING PORTION OF DRILL-HOLES.

1	130 × (40 × ¼)	or 10.0	= 1300
2	35 × (30 × ½)	or 15.0	= 525
3	60 × (20 × ¼)	or 5.0	= 300
4	50 × (20 × 1)	or 20.0	= 1000
5	40 × (20 × 1)	or 20.0	= 800
6	50 × (30 × ¼)	or 7.5	= 375
7	60 × (20 × ½)	or 10.0	= 600
8	42 × (30 × ¼)	or 7.5	= 315
		95.0	5215

This gives the value per cubic yard for this part area of 54.89c. In a like manner, the total area gives a value per cubic yard of 28.76 cents.[1]

To get a value of 37.69c. per cubic yard as calculated by Mr. Decoto, it is obvious that the ground would have to be dredged to take in the area enclosed

[1]This gives a difference of 8.93c. per cubic yard, or 31%, which might in some close dredging propositions change a calculated profit to a loss.

by the outside boundary lines shown in the sketch. It might be posisble for a dredge to work such a boundary, but it is improbable that the operations would be so conducted.

E. Bryant Thornhill.

Cobalt, Ontario, May 20.

Revision of the Mining Law

The Editor:

Sir—I have just been reading the article, 'Revision of the Mining Law,' by Frank P. Davis, in your June 13, 1914, issue. I have given this subject, particularly the location and title of quartz mining claims no little thought and study since the question of a 'Mining Code Commission' has been agitated, and I give Mr. Davis credit for advancing some good ideas in his fifteen different suggestions. Taking them in the same numerical order, I will present some of my views of the question, in a brief manner.

1. All mining locations to be made only by citizens of the United States.

2. Size of a full quartz mining claim to be 1320 ft. on a side (40 acres) and located relative to the legal subdivisions, if surveyed. In any event, all boundary lines to be north and south and east and west.

3. Location monument, with a legible notice, a true copy of the record, posted at the discovery work.

4. Boundaries to be plainly marked with stakes, or monuments, on all sides of the claim, so that they can be easily traced. Corners established with large prominent posts (6 in. square or more) set in mound of stone, at least 4 ft. above ground, giving name, number, and identity of the corner, with right to fence but not to encroach on public trails or highways.

5. Discovery work to consist of a shaft, adit, or open cut, not less than 10 ft. deep, and more if necessary, to expose the vein in place, and it *must* show a vein, to be a legal location. This work may be done at any point within the boundary of the claim, at the option of the locator, regardless of any 'centre line.' The position of this discovery work, with relation to the boundaries, must be accurately located and appear in the record, by giving the distance from all four lines of the exterior boundary of the claim.

6. Have location notice describe the location, as far as possible, by legal subdivisions, giving section, township, range, etc., so that it may be accurately located from the field notes of record. If it cannot be located and platted from the record it is not a valid location.

7. No extralateral rights, but to own all mineral within its vertical boundary lines.

8. Claim must be recorded within 30 days from the date of discovery, at which time the discoverer must post a temporary notice, bearing date of discovery, and declaring his intention to locate and record.

9. No overlapping of claims.

10. Fix a penalty for fraudulent dating. If the title to a claim has lapsed the original owner can only secure it again by paying up his back tax, as prescribed below, and not then if it has been located by others.

11. Let the first day of January be the date from which all locations are fixed, relative to the tax, etc., so there will be no confusion of dates. If a claim is located in 1914 the tax must be paid in 1915 or it is subject to location by other parties.

12. To pay a yearly tax, until patented, of a fixed amount, on each location, in lieu of the assessment now required. Said tax to be due in the second year of the location. This tax receipt to be proof of non-abandonment. Make all unpatented claims subject to this tax.

13. Proceed to patent under the same rules and regulations that exist today. Get your survey number and a U. S. deputy mineral surveyor to mark and establish the corners. It is absolutely essential to have these monuments correctly fixed, particularly so if it is a patented claim.

14. Accept no agricultural filings in known mineral area, or reserve all mineral rights, with surface restrictions, so they can be prospected. Fix a penalty for posting 'scare notices,' such as "No trespassing on these premises" on territory that is not absolutely owned. This keeps prospectors off.

15. If the above suggestions were adopted, I can see no reason why claims should not be located by proxy or power-of-attorney.

I believe in giving the prospector and locator every possible chance, but there are some of them who abuse their rights, which is made possible by the present laws. They get 'hoggish' or 'dog-in-the-manger' like. They won't develop their locations, in fact, they can't, nor will they let any other prospector in. I know of a case, and I dare say the same condition prevails, to some extent, in every mining camp in the West, where a prospector has 20 claims, and he has held them for years. Now, it is a physical and financial impossibility for him to do this assessment work legally, yet he keeps other prospectors away. In many cases he does not make a pretext of doing the assessment, but gets very busy at midnight of December 31, posting new location notices, in his own and other people's names. I think my suggestion in paragraph 12 would remedy this.

If a person should discover something near these '20 claims' it would be impossible for him to determine whether or not he was trespassing on one of them. The description, in the location certificate is so meager, indefinite, and consequently flexible, that it would be impossible to locate the position of any one of them on the ground. The course is generally given as northeast and southwest. If there is any tie at all, it is to a pine tree or a log cabin that has long since burned down. Hence my suggestion in paragraphs 4 and 6.

In paragraph 2 I suggest the size of a quartz claim to be 1320 ft. square. I do not think this is any too large, and it would be very easy for a prospector to locate it, so there would be no excuse for his not having a valid location. For example, he locates the S.E. ¼ of the S.E. ¼ of Sec. 16, T. 19, N. R. 6 E., M.D.M., etc. Or, if the

claim cannot be conformed to the legal subdivision, in this manner, he can measure off, from or to the section or quarter corner, as the case may be, any distance north, south, east, or west, to a starting point, and describe it as follows: Beginning at corner No. 1, whence the S.E. corner, Sec. 16, T.. R.. etc., bears E. 1000 ft., thence N. 1320 ft. to corner No. 2, thence W. 1320 ft. to corner No. 3, thence S. 1320 ft. to corner No. 4, thence E. 1320 ft. to corner No. 1, the place of beginning. Suppose half of the claim was in section 16 and the south half in section 21, it would be described in the same manner, only the starting point would be on a side line instead of a corner, viz.: Beginning at a point 1000 ft. W. of the S.E. corner Sec. 16., etc., thence N. 660 ft. to corner No. 1, and around to corner No. 4, thence N. 660 ft. to the place of beginning. These would be valid locations, affixed to and made part and parcel of the public survey. It is a wonder to me that something after this fashion was not adopted long ago. What is the public survey made for, if not just for this purpose; to locate and identify positively different tracts of land?

It would be possible to locate any claim desired, in this manner, so that it would cover the vein apex for the full distance. That is one reason for leaving the position of the location work optional with the locator, as suggested in paragraph 5. Another reason for this is so the locator may take into consideration the dip of the vein, relative to the vertical side lines, and locate his surface ground accordingly.

I have made particular mention of some of the features of our mining code, and, in my opinion, some of the worst things the prospector of today has to contend with, especially in the newer camps, where so many men make a practice of rushing in and staking all the ground possible and holding it for 60 or 90 days, or even longer, by re-staking it, without doing a tap, much to the detriment of the camp and a hardship to those who arrive later.

In many places I have even seen these stakes stuck in the snow. Paragraphs 8 and 10 are suggested as a remedy for this fault. And I believe if the time limit for recording was cut to 10 days, instead of 30, it would be still better. The law giving the locator 90 days to do his discovery work, survey, and record, in a way, was necessary, as it required some time to trace out the apex of a vein before it could be covered intelligently with the location. But with the claim square, as suggested, this would not be necessary, and a 10-ft. hole could be sunk in any ground in 10 days. This would mean that the 'stake hog' or 'ground hog,' as he might well be called, would have to get busy 'throwing dirt,' instead of trying to stake the whole landscape as a speculative enterprise.

As has been suggested, 'now is the time to holler.' Don't wait until the drill strikes the bottom of the shaft, and then shout, 'Look out below!'

CLARENCE K. COLVIN.

Forbestown, California, June 18.

What is the Matter With Prospecting?

The Editor:

Sir—From the point of view of an operator actively engaged in examining prospects with any promise, I would state that in my opinion the chief difficulty the prospector encounters is interposed by himself, in the form of prices and terms. These are often so severe that an examination is not justified, even on the basis of the rosy statements made. If the risk of the expense of an examination is taken, the matter usually boils down to the question of putting up cash for the privilege of putting up more.

When trade is quiet in real estate, railroad bonds, winter wheat, or mining prospects, there is always one underlying reason, namely, that sellers are asking more than the buyers can pay. The conundrum is not a difficult one from an economic standpoint. If the question were put in another form, namely: How shall we stimulate prospecting? I would say by making known prospects attractive to the operators.

If I were a prospector, and had a prospective mountain of ore, exposed at one or two points, and were sure of being able to find these points again, I would request an operator to examine it and offer him a year of development, giving him an option to purchase at from $1000 to $10,000, according to circumstances, this price to be paid within three years at a rate of not less than $25 per month. As soon as this deal was closed, and it would not take long if the one or two points of ore could really be found again, I would hunt for the next available mountain of ore and endeavor to close in due course a similar deal if such mountain were available. If my prospects were really interesting, I would hope to get a raise in my income of $25 per month once or twice a year, and come into an occasional bonus when some of the prospects proved to be more than interesting.

If I could not earn a good living on this basis, I would go into some other business, and from a safe distance, would amend my contribution to this topic. I would say it was not because prospects were held too high to be interesting to the buyer, that the business of prospecting was dying, but because there were not enough prospects to justify the search for them.

Unless more prospects are offered on terms which will justify examination and development, the art of prospecting will perish, and a post-mortem examination will probably show that it died of wilful starvation in sight of food.

OPERATOR.

San Francisco, May 29.

LOAD FACTOR in electric power being supplied to 115 classes of industries by the Pacific Gas & Electric Co. of California is 59 per cent.

COKE PRODUCTION of Kentucky in 1913 was 317,084 tons.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

INDIA, RUSSIA, AND BRAZIL produce 90% of the world's supply of manganese ores.

'WIRELESS' TELEPHONY is now used in the Lindsay colliery of the Fife Coal Co. in Scotland. Current is carried through the rails in the drifts. Four receivers weighing 50 lb. each have been installed, and each instrument has a battery of four cells producing current at 15-volt pressure.

A PROCESS for making pressure-sustaining coke containing a minimum of detrimental sulphur constituents, from coal, consists of adding to the coal before coking a phosphorous compound of lime, and coking said mixed mass. The process has been devised by Leon Franck, of Luxemburg, Germany.

PLUNGER PUMPS are made with several important adjuncts to permit of better operation, which may be described as follows: An air vessel, charged with air, which acts as a reservoir of energy. During the discharge stroke the air in the vessel is compressed. The energy, which is stored up in the compressed air, is given out again during the pause which takes place when the pump is changing the direction of its stroke. The water in the delivery column is thus kept in motion during the pause, and shock to the pump is reduced. The power required at the beginning of the stroke is also reduced as the force of inertia is eliminated, due to the water being kept in motion. Snifting cocks are used where the suction pipes are too small. If such is the case the water in the suction pipes rushes into the pump at a high velocity. This prevents the suction valve closing until the ram has made part of its stroke, and consequently causes a considerable amount of shock to the pump when the two columns of water come into contact. By using snifting cocks a certain quantity of air is admitted at each stroke. The air acts as a cushion to the water, and allows the valve to close at its proper time, thus reducing shock to the pump. The suction valve prevents the water from being forced back into the suction column during the discharge stroke of the pump. The delivery valve holds the water in the delivery column, and prevents it running back into the working barrel during the suction stroke of the pump.

GAS PUMPS for lifting water are coming into more general use. The Humphrey system, as installed to pump 180,000,000 gal. of water per day for London, with a fuel consumption not exceeding 1.1 lb. of anthracite coal per pump-horse-power hour, was described in the *Press* of June 28, 1913. Another Humphrey plant is to be erected at Mex, three miles west from Alexandria, for the Egyptian government. Certain lands in the district have become 'water-logged,' and it has been decided to drain Lake Mariut, having an area of 50,000 acres and 3 ft. deep, and reclaim the area under water. To do this, the lake water is to be pumped into the Mediterranean Sea, a lift of from 19 to 20 ft. from a drainage canal, over a narrow protecting ridge on the seacoast. Ten Humphrey pumps, eight of which will be sufficient to lift 792,000,000 gal. per day, are being made by Messrs. Beardmore and Messrs. Brown, Boveri & Co. Each machine will have a combustion chamber 8 ft. 8 in. diameter by 14 ft. high. The valve-box will be the same diameter and 7 ft. high, and is to have 100 valves of the hinge type, which will close on any obstruction without straining the hinges. The 'play-pipe' of the pump will slope upward so as to deliver water at the required elevation in the discharge basin. The pumps are started by admitting into the combustion chamber a mixture of gas and air. The Power Gas Corporation will supply an anthracite Mond plant capable of gasifying 44 tons per day, consisting of nine 6-ft. producers. The guaranteed consumption is 1.15 lb. coal per horse-power. Two Venturi meters will measure the water delivered from the pumps.

A DREDGE may be constructed to handle so many cubic yards of gravel per day, yet this capacity is entirely dependent on the skill of the winchman. He has control of the motors which drive the winches for side-lines,

CONTROL LEVERS ON YUBA NO. 14 DREDGE.

spuds, and other gear; also the main motor for driving the bucket-line, and lowering and raising the digging ladder. In his department, at the top of the dredge, is a switchboard and a large number of levers, by which he is able to control all operations of swinging the boat, stepping ahead, and digging gravel. The accompanying cut shows the levers on Yuba No. 14 dredge, California.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

WASHINGTON, D. C.

'Mineral Resources of the United States': More Appropriation Wanted for This Publication, Its Value Explained by the Director of the Survey.

Congress has not proved indulgent this year to the attempt of the U. S. Geological Survey to procure an extra $10,000 for the preparation of the report of the 'Mineral Resources of the United States,' allowing only $75,000 for the coming fiscal year as heretofore. An appropriation of $85,000 had been asked by the director, George Otis Smith. "Under this item," Mr. Smith told the House Committee on Appropriations, "there is taken every year a census of the mineral production of the whole country, which amounts at the present time to something over $2,000,000,000." Mr. Smith was asked how this census is obtained and thereby revealed some interesting facts as also the implied plans for the future by the Survey on this census. "It is done," he said, "by correspondence and a certain amount of visiting the different mining districts and especially of Western mining districts. The report is a very accurate statement of the mineral production of each year, by reason of the fact that we have a permanent force that is in almost constant correspondence with the individual producers. It is not like waiting 10 years and then getting in touch with the industry, for our statisticians are in constant touch with them. We believe that by the various checks we use, that is, by compiling not only the returns of the individual producers in the Western states, but by using the returns of the smelters to which the ores have been sent, and, then also, by using the double check of the statistics of the shipments which are furnished by the different railroad companies, that we have the truth of it. It may be surprising, but there have been instances where individual producers several years afterward have asked us what their production was for certain years, getting this from our books, and in some cases the return was based not so much on what the man might send in himself, but on what we learned through railroad shipments at the particular siding where his ore was loaded. We are more and more giving the public, or are trying to give the public, a fair statement of the mineral production of the preceding year on or near the first of January, that being the time that a good many people interested in the subject desire the statistics. We make these preliminary estimates, which are usually based on what we know of the eleven months previous, and then we estimate for the twelfth month. Then we are also trying to give to the public before July 1 the complete report, which gives the totals, including not only the state totals, but the county totals. Our printed report is issued first in the form of separate chapters which are devoted to particular products, like iron ore or coal or coke and later they are assembled in two volumes that make up the annual report. The work is steadily increasing by reason of the greater number of producers. I ask for an increase of $10,000 partly because I am not satisfied with the promptness with which we can issue the reports under the present appropriation, nor am I satisfied with the thoroughness with which we cover the whole field. With the additional money the telegraph would be more freely used to get the reports from the producers last to report. Sometimes the expensive part of a report is the last of one-half of one per cent, that is to get the men who are staying out to send in their returns. Ninety-nine per cent of the returns may be in, but a wait of several weeks is incurred to get the remaining one per cent. It is a decided advantage to have a geologist or clerk ready to go out from the nearest Survey office to solicit the returns in person. One such visit will keep a producer in line for several years, simply because he realizes the importance of the information to the whole industry. Offices of the Survey are in Washington, Denver, Salt Lake City, and San Francisco. The increase would also enable the employment of better men."

An inquiry by Congressman Mondel of Wyoming, as to why the statistics from certain states were lumped, brought an interesting and explanatory answer. The Congressman said he was especially interested in the showing of Wyoming. For instance after an industry, such as iron in a state was below 500,000 tons per annum that state was simply lumped in its iron with other states. "If there are only two producers in a state," explained Mr. Smith, "we will lump that state with some other state, because by giving the total production for two producers only we are giving each one of those producers information regarding the tonnage of his competitor." "What objection is there to the people knowing how much the Colorado Fuel & Iron Co. produces at Sunrise, in my state?" asked Congressman Mondel. "There is no objection," replied Mr. Smith, "unless the operators prefer to have their returns confidential. Our returns are usually confidential." Mr. Smith added that he was able to show that when Congress called for the figures of the individual production of large corporations supplying the U. S. Steel Corporation, 20 large producers were in the list. He said that the reports had practical value moreover as was shown in the case of a small miner in Missouri who was not satisfied with the prices of zinc he was obtaining and who asked of the Survey the range of prices for zinc ore. The Survey gave him a report showing the range of prices month by month, and in his return letter the miner said that through the report he had been able to get a considerable advance over the prices that the ore-buyers had been allowing him. "The big people do not need this kind of help so much as the small producers," said Mr. Smith. "The large copper mining companies, for instance, have an agency of their own whereby they keep monthly statistics. It is of course interesting and gratifying to us that when they started that system a few years ago they came to the Survey and took the geologist who was compiling the annual statistics on copper for this volume, and he has since been issuing every month for the benefit of those large producers the monthly figures on copper production." Mr. Smith was referring to L. C. Graton, secretary of the Copper Producers' Association. Legislation in Congress on mining continues to make no advance worth noting.

NEW YORK

Business Situation.—National Copper Mine.—Granby Consolidated.—Heinze Suits.—International Steam Pump Co.—Gold Hill Affair.

There seems to be something of a new undertone in New York markets. The past three years have constituted a long period of depression, a lane that seemed to have no turning. It would be too much to say that a turn in the lane is in sight. There are too many railroad receiverships and too many reorganizations obviously necessary, but there is be-

coming more and more evident a prevalence of the belief that the worst is known and has been adequately discounted, and students of underlying conditions are getting back to the position that the country's tremendous production spells prosperity. There are readjustments making and yet to be made. There are some reformations of spirit yet to be accomplished in financial circles, the lesson that service is the only work that deserves reward has been taken to heart by manufacturers, by railroad operators as distinguished from financiers much more fully than it has by the banking element that is still feeling the public disapproval. The stagnation of general business is typified by the copper situation. Domestic deliveries have been far below normal during all of the current year, while June makes a low record for the year, and a new low record for the corresponding month of the past six years. Surplus stocks show an increase, but it is so well recognized now that the producers are in control that there is no attempt to make market capital out of this feature.

At the National mine, in Idaho, while milling operations are still in the tuning-up stage, the process used has apparently overcome the question of the cost of oil, having reduced this from about 6 or 7c. to between 1 and 2c. per ton of ore treated.

The Granby Consolidated's fiscal year just completed has been a rather important one for the Company, as the management had in hand the task of putting the Hidden Creek property on a producing basis. The Company has maintained its dividend, but while producing some 22,168,614 lb. of copper the margin of profit has not been large.

Judging from appearances, the Heinze entanglement of various descriptions will receive 'Gordon knot' treatment in the near future. Heinze lies at his home ill. United Copper, Stewart Mining, Ohio Copper, are all in snarls, which, like the Amalgamated-Heinze fight in Butte, will not be unraveled, but will be cut. Unfortunately for Heinze, he no longer has an H. H. Rogers attempting to oust him from great properties, and the man who once fought the Standard Oil element in Montana to such a standstill is likely to make an almost unnoticed exit from the financial world.

The International Steam Pump Co. management has been attacked by John Drew in a suit alleging the existance of fraud in the deal by which the Pump company absorbed the Power & Mining Machinery Co. Quite recently the preferred dividends on two of the companies controlled by the Pump company were passed, and there has been some talk of the possibility of a receiver.

The 'regulars' down in the financial district have been enjoying many a good laugh over the publicity recently achieved by Walter George Newman of Gold Hill notoriety. Gold Hill was discredited on the New York Curb years ago, and Mr. Newman likewise. That he should be able to go to Washington and get officials there interested in his proposition is something of a triumph of nerve and perseverance. Gold Hill has been the vehicle of several spectacular market operations on the Curb, but as a mining operation it has been looked upon as a joke for years. Investigation into the use of official stationery resulted in wiping of the whole matter off the Senate Committee's slate as not important enough to take up time of the official, but in the meantime, Newman has reveled in the publicity so acquired. Inasmuch as gold production in the Eastern states amounted to but $165,733 in 1913, apparently Gold Hill is not the centre of a big camp. These figures given out by U. S. Geological Survey, included Alabama, Georgia, and South Carolina as well as North Carolina, within whose borders Gold Hill has its lair.

Extraction at the new Elm Orlu plant at Butte is from 96 to 97% of the zinc content of the ore. The Minerals Separation process is used.——Tests are being run at Anaconda on a 50-ton Minerals Separation flotation plant treating slime from Dorr thickeners. The first results are even better than was anticipated.

WARREN, IDAHO

BIG CREEK MINING DISTRICT: SITUATION, ELEVATION, GEOLOGY, AND NOTES ON THE MOSCOW, MCRAE-GOLDMAN, RED METAL, VICTOR-GLASGOW, GOLD COIN, AND PROBIGLO MINES.

The Big Creek district is situated in Idaho county, about 30 miles from Warren, and 60 miles from Thunder City. Minerals have been found in an area of about 17 miles north and south by 8 miles east and west, and which contains a large variety of base and free-milling ores. The district is approached from the railroad at New Meadow and Thunder City, both of which are branch terminals, over state wagon roads. Yellow Pine, the nearest settlement, is in the southern part of the district, and is reached by wagon road from the Short Line railroad at Thunder City about 50 miles distant. Approximately 30 miles of the Yellow Pine road is in the National Forest Reserve, and is well kept up. This part of the road is well constructed and

MAP OF IDAHO.

is ideal for automobiles, the grades being easy; but the other part of the road has been allowed to get in a bad state of repair. At the time these notes were written the county was doing some extensive repairing. However, in summer time the stage easily makes the through trip. Elevations of the district vary from 7100 to 9400 ft. above sea-level, and is on the extreme heads of Profile creek, Big creek, and Logan creek, which has a large amount of timber and water-power in many places. Snow in this region begins to fall late in October, and lies there until May, but most of the heavy mining is done in the middle of winter. The district, as a whole, is one of the most picturesque in the state, the innumerable water-falls, lakes and mountain peaks can be rivaled in few places. Yellow Pine is an ideal spot, there being an abundance of yellow pine saw timber there, with plenty of hunting and fishing and may some day be a great resort. The northern route into this mineral belt is over the old South Fork and Warren road which connects with the Pacific and Idaho Northern railroad at New Meadow 90 miles distant. This road crosses three high summits, one of these summits is over 9000 ft. high, and the

other two are over 7000 ft. The road as a whole is one of the worst in the state, and the expenditure that would be necessary to put it in shape for heavy hauling would build a good road from Yellow Pine through the entire district.

The geology of the district is interesting and the exposures of formations afford good opportunities to study the rocks. These are chiefly altered granite, cut by late intrusive dikes. The veins are from 2 to 200 ft. wide, and there are three distinct veins which traverse glaciated benches, which, in many cases, have been eroded and left the veins standing in bold relief. The occurrence of the intrusive dikes is quite general, and they are found in numbers ranging from 2 ft. in thickness to great masses. Although the formation is cut up by numerous fissures it is not badly faulted, the orebodies being generally found in place.

The so-called Moore 'bonanza' in the Moscow mine is 250 ft. wide, as has been determined by shallow surface cuts, and a good deal of free gold may be obtained from the more favorable gangue throughout the entire width by panning. The deposit, on this group of claims, has been traced for over a mile, and at one point has been opened by a cross-cut adit 200 ft. long, and has obtained a vertical depth of 150 ft. Two raises have been driven to the surface, and around these a 'glory hole' has been opened. The adit dump has been connected by a rope tramway hung on stumps to a five-stamp mill at the foot of the mountain. With this crude affair the owner makes a good living. The ore is free milling to a depth of 50 ft., when it changes into a rich sulphide. The glory hole has produced about 1500 tons of ore that averages $5 free gold per ton. A few samples taken from the sulphide horizon in the main adit assayed $5 in gold and silver, 85% of the value being gold. Some cyanide tests made on some of the concentrate show an extraction of 96% by grinding and agitation 8 hours in an 8-lb. solution. During the past season some well known engineers sampled this property, and one sampling of 150 ft. of the main adit gave an average of $3 per ton; while the zone 60 ft. wide, of more heavily mineralized ore, is reported to have averaged $4.40 per ton.

Continuing north from the Moore bonanza, another large body of ore is in the McRae-Goldman claims, shown by thick bands and a network of honey-combed quartz and gangue, 100 ft. wide by several hundred feet long, which yields by panning $5 to $20 gold per ton. This property is also being developed by the owners by a cross-cut adit to determine its width and average value. The claims are parallel with a large quartz vein containing some small streaks of rich ore, which were the basis of development work and a lot of wild-cat stock flotations in the early history of the camp.

The Red Metal mine, on the west vein, has a large body of brown-stained quartz which contains some sulphide and gold and a small percentage of copper is of great width. On the hanging wall side of this vein, a 5-ft. body of silver ore has been opened by two cross-cut adits to a depth of 100 ft. In 1905, the owner extracted five tons of ore from an 18-in. streak on the hanging wall, and shipped it to the Tacoma smelter, returning over $200, and 1 oz. gold per ton. The owner is now taking out a few tons which he expects to ship by parcel post.

Continuing on the same vein north to the Victor and Glasgow groups of claims, the ore is similar in character, but the gold content is much higher. In some places on these claims this is up to several ounces per ton. In several openings on the surface, small amounts of free gold can be obtained by panning, and from a shaft which is down 25 ft., ore has been extracted which assayed several ounces per ton. The main vein on this bench dips about 70° east, and several small stringers varying from 1 to 5 ft. are dipping into the main vein at an angle of about 40°. The intrusive dikes are numerous here. The owners of this property are driving a long cross-cut adit which will cut this vein system over 200 ft. below the outcrop. Another adit has been driven in the mountain lower down and has cut the centre vein of the district, showing a body of sulphide ore 150 ft. wide from which assays yield $5 per ton. This property has over 800 ft. of development done.

The Gold Coin mine is situated on the east side of Profile creek, and consists of a large deposit of brown oxide ore which assays well in gold. This vein traverses a glaciated bench and is cut by numerous porphyry dikes, and free gold can be obtained by panning. Lead-silver ore is also found in numerous small streaks which often lie directly parallel to stringers of siderite, and which seem to be feeding into the main body of brown oxide. At the foot of this mountain placer gold is found in profitable quantities.

The Probiglo Mining Co.'s property consists of four quartz claims and one placer claim, and is situated due north from the Victor claims. The vein on this property is 150 ft. wide, as proved by several surface trenches, and gives fair assays in gold and silver along its full length. Several rich streaks of gold-silver ore have been cut between the enclosing vein material, varying from 4 to 12 in. wide and assaying high in gold and silver. The Company is planning to ship several tons of rich ore this summer, and will probably build a small mill. By driving an adit in from the foot of the mountain a depth of 2000 ft. can be obtained.

Among other properties of the district, in various stages of development are the Laufer and Davis, Independence, and Copper Camp.

For cheap power resources the district is unexcelled, as it has a number of streams which can be made to develop 50,000 hp. at moderate cost. Big creek, in connection with Profile gap, affords comparatively easy railroad construction from the main Salmon river, and up the middle fork to southern Idaho. The ultimate construction of a branch over the proposed line would come up Big creek and open up the entire district to railway transportation.

DEADWOOD, SOUTH DAKOTA

ACTIVITIES OF THE DEADWOOD BUSINESS CLUB IN MINING AND FORMING THE HEIDELBERG MINING CO.—THE HOMESTAKE'S NEW HOIST.—HIDDEN FORTUNE AND TROJAN.

In the summer of 1913 the Deadwood Business Club thought that by developing some promising mining prospect a stimulus might be given to the general mining conditions of the district. After considerable investigation on the part of a special committee appointed for the purpose, it was decided to do the first work on the Heidelberg property, in the Two Bit district. The owners offered an attractive proposition, namely, to give a one-half interest for $5000, with the agreement that the money be spent in development. Work was undertaken in August, 50 citizens of Deadwood each agreeing to contribute $100 in 10 monthly payments of $10 each. Administration of the funds and development was turned over to five trustees, two representing the owners, two representing the subscribers and these four selecting the fifth member. Payments on subscription commenced August 23, and the final payment was collected on May 23, last. During the 10 months' operations, 380 ft. of development was done in new ground, besides enlarging and timbering in a substantial manner the main adit following the ore-shoot. In the course of the work there was removed, sorted and shipped 46 tons, dry weight, of ore which netted above treatment and transportation costs, $371. In addition a quantity of ore of milling grade was piled on the dumps. Since this time (May 23) about 70 tons additional has been shipped, a large proportion of which was in the bins at that time. The ore is a typical refractory siliceous material, similar to that mined in the Bald Mountain district, occurring in the upper Cambrian shales. The ore is principally sand shale enriched from a siliceous 'vertical.' This vertical, which is an average of 1 ft. in width, has a course of north 25° east. The sand shale is enriched on either side of it for a distance

of 1, 2, and 3 ft. It is 1 to 3 ft. thick and above and below it is lime shale, carrying small gold content. Development along the vertical discloses its continuity for over 300 ft. Should this vertical be found to extend downward to the basal Cambrian quartzite, it is quite probable, judging from experience in other districts, that a considerable body of ore may be found.

To provide further funds for the exploration of the ore-body, a corporation with a capitalization of 500,000 shares of a par value of 25c. each has been organized. Of the capital one-half, or 250,000 shares, was issued in payment for the property, and the balance placed in the treasury. Of the property purchase stock, one-half, or 125,000 shares, was issued to the original owners, and the other 125,000 shares equally divided among the subscribers to the development fund, so that each man who paid in $100 will receive 2500 shares of stock. Officers of the Heidelberg Mining Co., the name selected for the corporation, are: Geo. V. Ayres, president; John Treber, vice-president; J. Goldberg, treasurer; and W. L. Treber, secretary. The directors are: N. E. Franklin, president First National Bank; D. A. McPherson, cashier First National Bank; Geo. V. Ayres, hardware merchant; J. Goldberg, grocer; N. J. Thompsen, lumber dealer; A. T. Roos, superintendent of property, and John Treber, wholesaler.

For several weeks, steel for the new hoist house and headframe at the B. & M. shaft of the Homestake company, has been arriving, and shortly the first consignment of machinery is expected to be delivered. Foundation work is well in hand. It is of massive construction, in some places the cement, reinforced with railroad iron bolted into the solid rock, steel cables and other steel materials, will be over 20 ft. thick. The new hoisting engine is of the compound-condensing type, built by the Nordberg firm, and is one of the largest hoisting engines ever constructed. The machine, after its completion, was erected in the Nordberg shops, and has been dismantled for shipment to Lead. It is equipped with two clutched reels to carry flat rope ⅝ by 7 in. It is designed to handle 12,000 lb. of ore from a depth of 3200 ft., using skips in balance. It has a gross weight of over 1,000,000 lb., and will require 24 freight cars to deliver it in Lead. Steam to operate it will be secured from a boiler plant close to the C. & N. W. tracks. This plant will also furnish steam for an electric generating station. Foundation work on the boiler plant is progressing rapidly, and it is planned to have the new hoist in full operation by the end of the present year.

By the purchase of the Hidden Fortune 40-stamp mill, the Golden Reward company will be enabled to increase its milling capacity to 400 tons per day. The purchase was made from the Homestake Mining Co., which came into possession of the mill a year ago, when it took over the Hidden Fortune property. The Homestake removed some equipment from the plant, but the bulk of it passes to the Golden Reward. In the mill was installed a full complement of cyanide tanks, piping, crushers, and considerable miscellaneous material. The building was well constructed, and contains a large amount of lumber which will be used. The Golden Reward company has already started to remove the plant to its millsite in Deadwood. With this addition to the capacity of its milling facilities, the Golden Reward will rank next to the Homestake as a gold producer in the Black Hills. Numerous improvements in the plant are under way, including a tube-mill, Trent replacing tank, classifiers, etc., so that even better work will be done in the future.

At the Trojan a small streak of sylvanite ore was recently discovered that gave high assays in gold. Roasted specimens were as fine as the best Cripple Creek ever produced. The Company's mill is steadily operating on a good grade of material, and shipments are regularly going forward to smelters. The Company is in an excellent position financially. It is a close corporation, and does not publish statements of its earnings, but they are known to be good.

JOHANNESBURG, TRANSVAAL

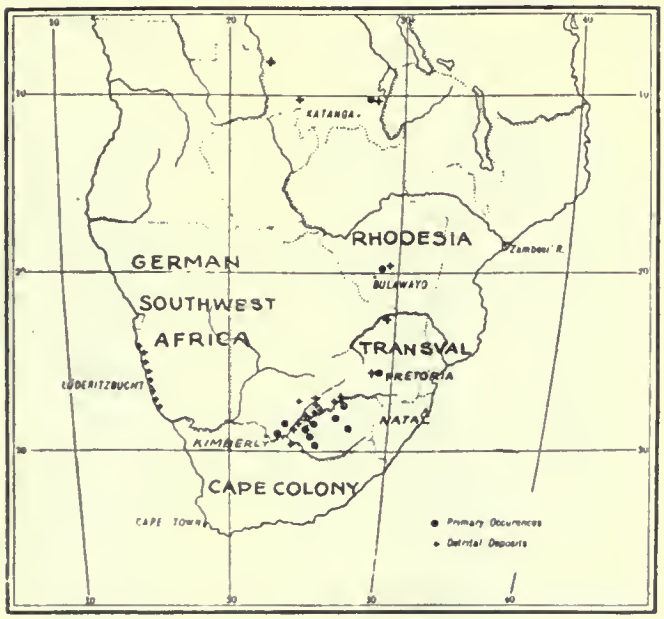
BARNATO, ALBU, AND CONSOLIDATED MINES SELECTION GROUPS OF MINES.—THE FAR EAST RAND.—DIAMOND MINING IN SOUTH AFRICA.

The feature of the first week in June here has been the large number of company meetings held. The companies controlled by the house of Barnato were particularly prominent, as this is the only group able to report substantial progress during the year. The reason for this may be found in the fact that until a few years ago this was the most backward of any mining group on the Rand, its properties were becoming almost derelict and the most antiquated in equipment. A few years ago, a change in the policy of this group was made, the Modderfontein Government Areas were secured, the Langlaagte properties were taken in hand, and some attempt made to bring the other mines more up to the mining practice of the Rand. The result now is that after the Eckstein group, the Barnato is one of the leading mining concerns on the Rand, and with the exception of their oldest mines, can compare in a satisfactory manner with those of any other group. There is, for instance, the Van Ryn Deep mine, which made a working profit of £105,022 during 1913, the working costs averaging practically $4.80 per ton. Much better results may be looked for during the current year, as working costs are declining and the gold recovery likely to go up to $8.40 per ton. Nearly 2,000,000 tons of profitable ore is developed in the mine, giving an average value by assay of $8.68 per ton. The Consolidated Langlaagte is another Barnato mine, which during the year has done exceptionally well. Working costs have been reduced 24c. per ton, while the profitable ore reserves are estimated at 2,194,408 tons worth $7.40 per ton. Like the Van Ryn Deep, this is another Barnato mine likely to yield even better results this year. The Government Gold Mining Areas at Modderfontein are also improving in the matter of development, ore reserves at present being about 1,250,000 tons averaging $6.35 per ton. It is to these three mines that the Barnato house is looking for most of the improvement in the immediate future, and no doubt they will more than make up for any marked decline the older mines of the group will show for some time to come.

The Albu group of mining companies also held their annual meetings during the week. The most promising of these is the Meyer & Charlton, which at the present time has the highest recovery value of any mine on the Rand, while working costs are being reduced. Several of the mines in this group continue somewhat under a cloud, notably Cinderella Consolidated, New Goch, and the Rand Collieries, and it looks as though some time will elapse before the necessary capital will be obtained for such undertakings as Cinderella Consolidated, Steyn Estates, and West Rand Consolidated.

The Consolidated Mines Selection group has also held meetings during the week, without, however, having anything particularly cheerful to report. Brakpan, the principal mine of the group, did worse than usual during the year, development assays falling away considerably; but during the first few months of the year quite one-half of the ore developed has proved unprofitable. The Springs mine seems to be opening fairly well, but the ore here is somewhat erratic. A fair proportion of the ore developed proved unprofitable, but there seems every probability of the mine falling little short of the Brakpan, underground conditions being somewhat similar on both properties. The Springs mine is situated nearly in the centre of the Far East part of the Rand, which is expected to do much to restore its prosperity, and to enable the Rand to again report progressive gold outputs. When, however, the Daggafontein, sinking about six miles farther east, reaches the 'reef', about the end of the year, the true value and prospects of the Far East Rand will be better known.

Diamond mining in South Africa has recently suffered financially from the evils of over-production, especially since the discovery of diamonds in German Southwest Africa. At one time the diamond mines at Kimberley had practically the whole of the world's diamond markets at their mercy; but recent discoveries of diamond mines in other parts of South



MAP SHOWING DISTRIBUTION OF DIAMONDS IN SOUTH AFRICA.

Africa have put quite a different complexion on the diamond mining industry. The Transvaal, with its Premier mine near Pretoria, can now boast of possessing one of the largest and most important diamond producers in the world, while the increasing production of alluvial diamonds in Africa has somewhat complicated the markets. So great has the diamond production of Africa become, that a conference was to be held in London during June, as mentioned in this journal of June 6. During May, Rand mines treated 2,196,287 tons of ore averaging $6.30 per ton, the lowest average in the last twelve months. Working costs were $4.08 per ton, which was equalled in January, 1910. Total profit for the month of May was £1,011,968.

JOPLIN, MISSOURI

STATE AND NATIONAL GEOLOGISTS CO-OPERATE IN EXPERIMENTAL WORK.—MINING ORES FROM SURFACE DOWN.—NOTES ON THE DISTRICT'S MINES.

H. A. Buehler, state geologist of Missouri, C. A. Wright, connected with the U. S. Bureau of Mines, and other geologists and mining engineers who are connected with both the state and federal departments of mining and geology, have established headquarters in Joplin, and a campaign of experimental work which will cover many months is being planned. Flotation processes will be tried out, this feature of the work being considered of much importance in view of the fact that the recovery of zincblende has never been what would be considered thorough, and therefore anything that will tend to bring about a more perfect recovery will be heralded as a great boon to the local industry. The study of the geology of the district, the character of the ores, the details of mining and milling, will be given due consideration, and interesting reports on the work thus undertaken will be looked for with much enthusiasm by local operators and others interested in the district. The oil flotation process has been tried at only one place in the district, namely, at the property of the Underwriters Land Co., west of Joplin, where a small plant is being operated by Hays & Co. The result of the experiment is being kept secret. Sludge from the Priscilla mine of the Underwriters company is being handled.

Modern pumping equipment is succeeding in draining the Lone Elm bottoms, in the northwest part of Joplin, where old types of pumps failed, and as a result operators are now getting into ground that has been under water for many years, and are even going far below the old levels worked. Also, some shallow development of importance is being conducted, work at one or two points being done from the surface down in the form of strip pits. This shallow work is being done where the ore is found within four or five feet of the surface. Plans for the construction of a mill to handle the shallow ore, and also to do custom milling from other mines on the lease, are being completed. The lease is held by the Lone Elm Development Co. and includes 330 acres of the Picher Lead Co.'s land and property of the Granby Mining & Smelting Co. About twenty small operators are at work. Two large pumping plants are maintained, the ground being drained to a depth of 120 feet.

Missouri will have a mines and mineral exhibit at the Panama-Pacific Exposition which will cost between $6000 and $7000, and detailed plans for the arrangement of the various displays have been completed by Otto Ruhl, of Joplin, and forwarded to John L. McNutt, of Aurora, chairman of the state commission having the Missouri exhibit in charge. A floor space of 50 by 100 ft. has been allotted for the Missouri display, and this will be used in a manner which will bring forth the mining industry of this state in an attractive manner. By a series of progressive displays, the visitor will see the prospecting, mining, milling, and smelting methods from the time the churn-drill begins to operate until the finished metal is produced. A complete concentrating plant of 25-ton daily capacity will be in steady operation. Concentrate will be produced from this mill just as it is from the larger plants of this district. The exhibit will also take in the disseminated lead industry of the southeastern part of the state, and the iron, copper, and coal mining of different portions of the state.

The Pocahontas Lead & Zinc Co.'s mill in the Thoms Station district, once a heavy producer, has been converted into a tailing mill by Bendelari & Funk; tables have been installed and various changes made in the equipment of the mill by which the plant will be in shape to handle the tailing. The shafts of the Company's mine are still sealed, although it is more than likely that the disastrous fire which broke out in the heavily timbered portions of the ground has long since subsided. It is said this famous old producer may not be reopened, as the land-owner, Miss Margaret Murphy, has refused to permit the pillars of the mine to be withdrawn. The pillars are rich in ore. This mine, in barely two years' operation, is reported to have netted Miss Murphy nearly $85,000 in royalties. She received a royalty of 10% of ore sales.

Improvements at the Wingfield mine, on a 50-acre lease of the Bowman, Scott & Ware land, north of Webb City, will mean increased production from this property, which already is handling 1000 tons of ore per day and which ranks as one of the heaviest producers of blende concentrate in the district. The mine is operated by Charles T. Orr and associates. The same company operates the Bertha A. mine, on the adjoining property owned by the Newell-Morse company. An old shaft at the Bertha A is being placed in commission again, and the output from this mine also will be increased.

At the beginning of July, zinc blende was weak at $37 to $40 per ton, basis of 60% metallic zinc, compared with $41 to $44 basis for the corresponding period of 1913. Calamine is strong at $22 to $23 per ton, basis of 40% metallic zinc, or about $1 stronger than for the corresponding week of 1913. Lead ore is dull at $46, basis of 80% metallic lead, compared with $52.50 for the corresponding week of 1913.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ARIZONA

Cochise County

Various mine contests were held at Bisbee on July 4, with the following results: Nipper drilling contest: first prize of $250 won by Robert Lyons, Andy Hooks, and Harry Lyons, who drilled 49 in. in 15 min., followed by Lawrence Ligon, Louis Oites, and Mitchell Bogice, winning the second prize of $125 with 32 in. This team had trouble with their steel breaking and lost considerable time. In the stope machine-drilling contest the first prize of $75 was won by Albert Peterson, who drilled 72⅞ in. The second prize of $50 was won by A. D. Fenwick, drilling 72⅜ in. In the timbering contest the first prize of $100 was won by Johnson and Butbrae in 13 min., 57 sec.; also most points for having set level, plumb, and square, also for placing blocks and wedges. The second prize of $50 was won by Jacobson and Martin in 17 min., 40 sec.; also second best on points. There were four entries. In the first-aid contest the first prize of $75 was won by the Czar team, Pat Nanna, captain. The second prize of $40 was won by the Gardner team, Francis Webster, captain. There were three entries. There was a difference of only one point between these teams and the judges had considerable trouble in reaching a decision. In the mine-rescue contest the first prize of $75 was won by the Calumet & Arizona team, Walter Haile, captain, and the second prize of $40 by the Copper Queen team, Thomas Stetson, captain.

Gila County

(Special Correspondence.)—Underground work at the Miami mine in June totaled 2910 ft., while 106,312 tons of ore was milled.——Lining of the Inspiration main shaft is the most important work at the mine. Underground bins have yet to be cut out. That at 600 ft. will have a capacity of 3000 tons.——Slag foundations are being poured for two of the reverberatory furnaces of the International company. Concrete amounting to 400 cu. yd. is being poured for the blowing engines' foundation.——Work on the Magma concentrator at Superior is well ahead. Electric power from Roosevelt has been available for some time. It is probable that a long aerial tram will be constructed from the mine to the smelter being erected at Miami.

Miami, July 10.

Competitive tests are being made at the Inspiration between Minerals Separation and Callow flotation plants. Results have not been made public. A. M. Cobb has been elected the first mayor of Miami.——The new Aldrich electric pump is working at 1800 ft. in the Old Dominion mine. This and the Arizona Commercial mine are to be connected on the 1200-ft. level. The basic converter has been at work for a year without relining, producing 32,000,000 lb. of copper.

Mojave County

During June the Tom Reed 20-stamp mill and cyanide plant produced gold worth $106,000. Rich ore is being mined from the 500-ft. level of the mine.——Good ore is being opened at 400 ft. in the Nevada-Arizona mine.——A mill is being erected at the old Fay mine.——The Schuylkill mine has been leased to California and Oregon men.

CALIFORNIA

The State Mining Bureau has distributed copies of *Bulletin* No. 67, 'Minerals of California,' by Arthur S. Eakle, consisting of 226 pages and an index. This work is just off the press, and should be in the hands of all California mining men. A list in 1866 included 75 minerals, another in 1884 included about 150, while the present work includes over 300, with many sub-species and varieties. A bibliography on California minerals is included. The book is divided into the following chapters: Native Elements; Sulphides, Arsenides, Selenides, Tellurides, and Sulpho-salts; Haloids; Oxides of Hydrogen, Silicon, and Semi-metals; Oxides of the Metals; Carbonates; Anhydrous Silicates; Hydrous Silicates and Titano-Silicates; Phosphates, Vanadates, etc.; and Sulphates and Hydrocarbons. Chapter XII covers minerals arranged according to the elements, and mineral distribution by counties. With *Bulletin* 585, 'Useful Minerals of the United States,' recently published by the U. S. Geological Survey, mining men have two very useful books.

The report of the statistician of the Industrial Accident Commission of the State of California for the first six months of 1914 has just been published. It shows some startling figures relative to the heavy toll of industry in terms of human lives and bodily injuries. A total of over 26,000 accidents has been reported to the Commission during the half-year ended July 30. Of these, 25,475 resulted in temporary disability, approximately 600 caused permanent disability, while 223 resulted in death. During June alone over 7500 accidents were reported, 10 of which were death cases, while 184 caused permanent disability.

Nevada County

The Red Ledge mine has been bonded to a New York syndicate, headed by W. F. Meeks, for about $150,000.

San Bernardino County

Sixteen suits by Colton orange-growers against the California Portland Cement Co. have been settled for $116,831. By agreement, the Company purchased 135 acres of land adjoining its property for $92,450, an average of $685 per acre. This will permanently end all suits. The Company's plant has a capacity of 5000 bbl. of cement per day, and it is proposed to increase this to 9000 bbl. at an expenditure of $1,000,000.

Sierra County

There are 35 men working at the Croesus or Plumbago mine, and high-grade ore is being extracted.——The Independence shaft is down about 300 ft.——Some good shoots of ore have been opened in the Kate Hardy mine.——Work is to be started by M. W. Davis and associates on two placer locations on Oregon creek. A gravel channel is capped by lava, but good yields are expected.

Tuolumne County

A prize of $200 for drilling at Sonora was won by W. Pedro and Fred Marcus, who put in a hole 37 in. in 15 minutes, followed by J. Page and F. Bartlett with 34⅞ in; J. and T. Lumsden with 32⅛ in., and G. Zackovich and J. Burbank with 31 inches.

COLORADO

Clear Creek County

A large station has been cut at the 860-ft. point in the main raise of the Capital mine. A good deal of water is flowing from this ground. An adit has been driven 610 ft. to meet this raise. Lessees are busy in the various sections of the mine. The Westinghouse mine locomotive, working in the main adit, gives no trouble.——Eighteen inches of

lead-copper ore has been opened in the Onondaga mine.——Retimbering is being done in the Colorado Central.——Ore has been shipped from the Santiago.——The Sutton, Steele & Steele dry concentration process may be installed in the Linn mill by C. E. Pughe.——Denver people are said to be trying to jump the Ramsdale claims on Bard creek.

SAN JUAN COUNTY

The Buffalo Boy mine, at Silverton, is again being sampled. ——Lessees at the Ledge mine are preparing to unwater the workings.——Under foreclosure proceedings, the Gold Prince

IN THE SILVERTON DISTRICT, COLORADO.

mine, mill, and tramway were recently sold to the Federal Trust Co. of Boston.——The San Antonio Mining Co. is being reorganized.——Twenty men are working at the Hamlet mine. ——Mines in the district produced 420 tons of smelting ore and 18,720 tons of concentrate during June.

TELLER COUNTY (CRIPPLE CREEK)

Twelve men are laying track, cutting a ditch, and doing other preparatory work at the Roosevelt drainage tunnel. Connection was made from the heading of the tunnel, 2600 ft. beyond the El Paso company's main shaft. The air was fair.——Trouble on the Short Line from Cripple Creek to Colorado Springs is hampering ore shipments.——The Last Dollar mine is again being operated.——Rain interfered with July 4 sports to some extent. In the drilling contest, Carroll and Gay carried off the first prize of $100, in double-hand work, drilling a hole 32 in. deep in Gunnison granite in the alloted time of 15 minutes. Hart and Adams, who drilled first, received second prize, drilling 27⅞ in., while Lund and Gustafson were third with 25 in. In the single-hand drilling contest John P. Hinds carried off first prize of $50, drilling 16⅛ in., William Fabry was second with 12½ in., and F. C. O'Neal was third, only putting his hole down 8 inches.

IDAHO

SHOSHONE COUNTY

Drilling contests at Wallace on July 4 resulted as follows: Four teams drilled, and St. Germain and Rossman of the Eugene R. Day ranch at Osburn won with 34 in., Morrison and Walters of the Tamarack mine were second with 30⅞ in., Stokes brothers of Osburn third with 30⅜ in., and Porter and Kinzella, of Butte, fourth with 29⅝ in.——At Wardner the contest was won by St. Germain and Rossman, who defeated five other teams, drilling 37⅝ in. in 15 minutes. The second prize of $100 was carried off by Morrison and Walters of Wallace, while Spridell and Furze took third place. The mucking contest was won by Herman and Johanson, and the log-sawing contest was won by Jess Dragon and Charles Anderson of the North Fork.

MICHIGAN

HOUGHTON COUNTY

The cost of maintaining the militia in the copper country during the strike last winter amounted to $405,000, it was announced on July 10.

MONTANA

About thirty mining districts in southwestern Montana are described in a report just issued by the U. S. Geological Survey as *Bulletin* 574, 'The Mining Districts of the Dillon Quadrangle, Montana, and Adjacent Areas,' by A. N. Winchell. The area described was of great importance in the early development of Montana, for it was the discovery of gold in the streams of this region that led to the influx of population and the eventual settlement of the state. The Dillon quadrangle comprises about 3200 square miles; the Butte copper-mining district is immediately north of it, and indeed two of the Butte smelters are within it. The projected Butte, Wisdom & Pacific railroad, upon which construction is soon to commence, will tap certain of the districts described in Mr. Winchell's report, notably the Elkhorn and Vipond districts in Beaverhead county.

The metalliferous mineral resources of the Dillon quadrangle and adjacent areas include gold, silver, copper, and lead, and smaller quantities of zinc, iron, manganese, and tungsten, and their distribution, mode of occurrence, geologic features, and origin are discussed in Mr. Winchell's report. The metallic ore deposits of the region occur in about thirty more or less well defined districts, and these are described individually. The report forecasts the future of the mining industry in the region, suggesting the probability that placer deposits were not destroyed but simply buried by the flows of basalt. If they are not too deeply covered by volcanic ash and lava flows, it is possible that they may in the future supply the material for extensive mining operations.

NEVADA

According to F. M. Manson, general manager of the Western Ore Purchasing Co., mining conditions throughout Nevada are exceptionally good, and greater activity is looked for. The Goldfield district leads others in ore shipments to the Company's plants. The Seven Troughs district is developing well. When the Nevada Short Line, or Codd railway, to Rochester is finished, large shipments should be made from that district. The Bullion, Haystack, and Pine Creek districts are quite promising.

The itinerary of Bureau of Mines Billings mine-rescue car No. 5 is as follows: July 13 to 18, Goldfield Consolidated, Jumbo Extension, and Florence mines; July 20 to 25, Tonopah Mining, Montana Tonopah, Belmont, West End, Tonopah Extension, and North Star mines; July 27 to August 1, Round Mountain mine; August 3 to 8, Pittsburg Silver Peak mine at Blair; August 10 to 15, Nevada Wonder mine at Wonder; August 17 to 22, Nevada Hills mine at Fairview; and August 24 to 29, demonstrations to university mining students and railway employees at Reno and Sparks.

ESMERALDA COUNTY

Great interest was shown in the double and single-handed

rock drilling contests held at Goldfield on July 4. In the doubles, Schram and Olson won first prize ($600), drilling 56 1/16 in.; McCann and Collins, second ($200), 56 3/16 in.; Impola and Hokken, third (two suits of clothes), 54 1/8 in. In the single handed contests, Paul Malli won first prize ($150), drilling 33 1/2 in.; Pete Vanola, second ($50), 30 1/2 in.; and Steven Mitrovitch, third (one suit of clothes), 28 3/16 inches.

HUMBOLDT COUNTY

(Special Correspondence.)—Directors of the Rochester Mines Co. have extended leases of the Rochester Hills Mining Co. and Big Four Mining Co. one year, to December 7, 1915. The Four J's Mining Co., which adjoins the Rochester Hills, expires in July 1915. The Rochester Hills has cut a new vein in the Cawsten adit level, a vertical depth of 400 ft., which is believed to be the 'back vein' and has never been developed. The depth on the dip of the vein is 520 ft. The discovery was made in a cross-cut 40 ft. east of the shaft, where the vein is reported by the management to be 12 ft. wide. Five feet is worth $24 to $32 per ton, the balance of the vein being good milling ore.——A. A. Codd, president of the Nevada Short Line railroad, which is being constructed up Rochester cañon to the mine, states that track-laying will commence July 20, and that the road will be completed to the town of Rochester by Labor Day, when a big celebration is planned.——It is said that John F. Cowan, president and manager of the Rochester Mines Co., has financed a custom mill for Rochester ores, which may be built at Nenzel, the terminus of the Nevada Short Line on the Southern Pacific, where a reliable supply of water may be had. A Nevada syndicate, which is said to have secured power rights of the Lahontan dam from the U. S. Reclamation Service, is endeavoring to secure a contract to furnish electric power for the proposed plant.——The Rochester Hills and Big Four leases continue to ship 75 tons of ore per day. The Nevada Packard is shipping three to four cars per month, with an occasional car from other leases in the district. A feeling of optimism pervades the camp.

Rochester, July 9.

In June there was 1400 tons of ore worth $35,000 shipped from Rochester. The average value of ore produced in 18 months was about $25 per ton.

LINCOLN COUNTY

On account of the success of the chlorination process at Park City, Utah, a local syndicate is planning to use the process to treat the low-grade lead-silver-zinc ores of Pioche. Old dumps contain a good deal of lead-silver-gold ore.

NYE COUNTY

An excellent brochure, 'Tonopah: Past, Present, and Future,' has been published by Charles A. Stoneham & Co. of New York. It consists of 16 pages with good illustrations of mines and mills, and also claim maps in silver tint. The history of the camp is described, and all necessary details are given to enable mining men to understand the properties being developed and producing silver.——During the week ended July 4, the mines produced 9252 tons of ore worth $254,620. In the quarter ended May 31, 1914, the Belmont company's revenue was $829,962, of which $454,351 was profit. The available resources amount to $1,447,761. The West End Consolidated Co. has filed an answer to the Jim Butler Tonopah Mining Co. in the latter's suit concerning wrongful extraction of ore. During May the Extension made a profit of $19,090. There have been labor troubles during the past week at Tonopah, and it appears that the I. W. W. is about to make itself a nuisance as elsewhere of late. Extensive development is being started at the Jim Butler claims. The Montana mill is treating 150 tons per day.

STOREY COUNTY

The U. S. Bureau of Mines rescue car No. 5 arrived at Virginia City from Ely on July 6, in charge of E. Steidle and G. W. Riggs. On July 8 and 9 there was instruction on the 1000 and 2500-ft. levels of the C. & C. shaft with oxygen helmets, also in injuries of all kinds. As a result of this visit, two efficient teams have been developed here. The car left for Goldfield on July 11.

WHITE PINE COUNTY

A mine-rescue and first-aid contest was held at Ely on July 4 under the joint auspices of the American Red Cross and the U. S. Bureau of Mines. The rescue contest of $50 was won by a team from the Nevada Consolidated company's Veteran mine, captain J. C. Metcalf, with H. P. Carten, E. L. Vetter, W. J. Murphy, and Patrick Friel. The problem used in this event was as follows: Fire in miniature mine. Rescue team explores imaginary smoke area, rescuing miner overcome by gas and smoke; every safety precaution as practised by the U. S. Bureau of Mines being observed. In the first-aid contest of $75, the Copper Flat team won, captain C. H. Kay, with A. P. Buffington, R. F. Workman, W. R. Workman, and John Minnock. There were also Greek and Japanese teams from McGill, who were trained in army tactics in their respective countries. The Japanese team is probably the only Japanese first-aid team in America. Problems

ELY, NEVADA.

used in the drill were as follows. One-man events: (1) Miner loading round of holes; puts off shot; he is overcome by powder smoke; rescue patient and restore breathing; burned about face and chin. (2) Man found under fall of roof, suffering from following injuries: fracture of sixth, seventh, and eighth ribs on left side, fracture of left kneecap. (3) Miner starting hole with piston drill; helper struck in left eye by flying chips; cut eye, severe bleeding; falls back, spraining left wrist. (4) Man working in smelter severely burned on right side and right forearm by explosion of matte pot. (5) Brakeman on slag train slips on rail, engine runs over left leg, cutting it off 4 in. above knee; man severely shocked. (6) Demonstrate four methods of one-man carry, including assistance to walk. In the two-man events were to be shown three methods of two-man carry.

According to *Safety First*, the Nevada Consolidated company's monthly bulletin, there were no accidents at either the Veteran mine or concentrator, but at Copper Flat there were 15 disabling accidents. The large concrete central hospital at East Ely is described and illustrated in this bulletin.

OREGON

JACKSON COUNTY

(Special Correspondence.)—The Purkeypile mine, in the Gold Hill district, has been bonded by southern Oregon men. A stamp-mill and other equipment has been ordered from San Francisco. The mine's output to date is over $75,000. Gold Hill mines are fairly active, judging by gold receipts at the local bank.

Gold Hill, July 10.

UTAH

Beaver County

Sixty tons of gold ore, averaging $1000 per ton, is being mined from No. 1 and 2 levels of the Sheep Rock mine, in the Newton district. The Beaver Gold Mines Corporation owns this property and a number of claims adjoining.

Juab County

First-class ore amounting to 3656 cars or 182,800 tons, and worth $4,570,000, was shipped from the Tintic district during the first half of 1914. The shippers were as follows in carloads: Centennial-Eureka, 632; Mammoth, 605; Chief Consolidated, 483; Iron Blossom, 462; Eagle & Blue Bell, 325; Grand Central, 289; Gemini, 286; Victoria, 119; Gold Chain, 89; Beck Tunnel, 56; May Day, 55; Colorado, 49; Bullion Beck, 29; Dragon Consolidated, 28; Uncle Sam, 26; Scranton, 25; Opohongo, 15; Sharp, 11; Lower Mammoth, 8; Godiva, 9; Carisa lease, 12; Eureka Hill, 3; Yankee, 5; Tintic Standard, 1; Swansea Consolidated, 1; United Ore Sampler, 2; United Tintic, 4; Black Jack, 5; Ridge & Valley, 2; Victor lease, 3; Salvador lease, 1; E. L. Davis lease, 1; Leaver lease, 1; East Tintic Development, 2; Clift, 1; Sunbeam, 3; Minnie Moore, 4; Showers, 4; and Tesora, 1 car.

Small shoots of rich gold-silver-copper ore are found at 700, 800, and 900 ft. in the Grand Central mine, and two cars of this ore are shipped each month. About 100 tons in June returned the Company $10,000.——Electric equipment is being installed in the Gold Chain mine.

WASHINGTON

Okanogan County

(Special Correspondence.)—Two stamp-mills are now working in the Similkameen part of this county, both under the management of the United Mines, of which J. L. Harper is the leading man. At the Owasco are 10 stamps and Wilfley tables, and a ball-mill is being added to increase the mills' capacity to 60 tons per day. Concentrate sent to the Greenwood smelter assayed $90 per ton. The mill at Night Hawk has 20 stamps and four Wilfley tables, treating ore from the Caaba mine.

Nighthawk, June 20.

WYOMING

The total value of gold, silver, and copper in this state in 1913 was $84,474, an increase of $57,527 over that of 1912, according to the U. S. Geological Survey. There were 15 producing mines, of which six were deep and nine were placer. Silicious ore amounted to 3272 tons, and copper ore 964 tons. The yields were 1170 oz. gold, 957 oz. silver, and 385,239 lb. copper. Placer mines produced $1407. Four deep mines and three placer mines in the Atlantic City district of Fremont county produced $23,276 gold and 115 oz. silver. In Platte county, the Sunrise mine shipped a good tonnage of silver-bearing copper ore; and several cars of copper ore from the Green Hope mine. Wyoming has produced since 1867, $1,191,178 gold, 58,680 oz. silver, and 26,383,318 lb. copper, with a total value of $5,378,908.

CANADA

Alberta

(Special Correspondence.)—There have been several reports of oil and gas finds in the Calgary district, but most of them are unfounded. The Monarch well had a few 'drops' of oil. It is down 400 ft. below that point, with no further development. Work is being done at the Lady Betty well. There are several small anticlines between this place and the United States boundary line which are worth a test, but in the 4500 square miles examined by four engineers, there is no large field of value along the Rocky Mountain front.

Calgary, July 4.

The Lineham area near Oil City has been purchased by a Calgary syndicate for $150,000 cash. The oil excitement continues, and there are five exchanges open in Calgary.

British Columbia

Zinc ore production of Kootenai and Boundary mines in June was 655 tons, against 301 tons in June 1913. This ore goes to the United States. The Lucky Jim produced no ore last month, while the Rambler-Cariboo, Van Roi, and Standard shipped 82, 32, and 541 tons, respectively.

A good deal of work is being done in the Rocher de Boule district, according to *The Chalcopyrite* of Skeena Crossing. The Montana Continental Development Co., and the Hudson Bay Mining Co. have extensive developments planned and under way. An aerial tram is nearly completed by the former concern. A long shoot of ore has been exposed by trenching at the Fiddle Creek claims owned by Lew Knauss. An adit has opened gold-silver-lead-copper ore worth $39.60, the gold content being about $28 per ton. A 45-ft. adit driven in the Brunswick claims, has opened chalcopyrite, containing silver. Good specimens of bornite were recently brought in from Driftwood river.

A new copper furnace has been blown-in at the Trail smelter, making a total of four for the copper-gold ore of the Rossland district. The tonnage now required from the mines is about 1000 per day, against 600 to 700 tons formerly. In June, the Rossland mines produced 22,811 tons of ore.

Ontario

Mineral returns published by the Bureau of Mines for the first quarter of 1914 are as follows:

	Quantity.	1914.	1913.
Gold, fine ounces	61,032	$1,202,502	$1,030,910
Silver, ounces	6,519,860	3,549,556	4,040,450
Copper, tons	4,135	591,988	436,328
Nickel, tons	6,641	1,446,012	1,309,870
Iron ore, tons	4,536	12,928	25,695
Pig iron, tons	184,086	2,503,450	2,506,175
Cobalt, tons	33	8,898	.....
Cobalt and nickel oxides	248,001	168,965	120,500
Total	.....	$9,484,299	$9,469,938

Silver production of Cobalt showed a decrease of 680,198 ounces.

The Buffalo mill treated 6307 tons of ore in May, averaging 18.66 oz. silver per ton. There was 93,326 oz. recovered, and 173,747 oz. was paid for during the month.

Draining Cobalt lake will not commence until October, when all preliminary work will be finished. In five weeks or so further excavation will be made to lower the water about 6½ ft. The pumps and motors are now on the site.——The mill at the Temiskaming and Hudson Bay mine has been shut down. The mine became a steady producer in 1907. Dividends paid since 1905 amounted to $1,940,250, equal to 25,000% on the capital of 7460 shares.——At 100 ft. in the Cochrane mine, 3 to 5 in. of 2000-oz. ore has been opened. A 10-ft. raise is still in ore.——Development in slate at No. 4, and in conglomerate at No. 5 level of the Penn-Canadian has opened good ore.——The Dome mill treated 16,180 tons of ore yielding $62,109 in May.——The Nipissing high and low-grade mills treated 202 and 6672 tons of ore respectively in June, and the refinery shipped 619,316 oz. silver. No. 64 vein was cut at 900 ft., where it is from 4 to 7 ft. wide, but low grade.

MEXICO

Sonora

A Mexican pumpman, working at the Sierra de Cobre mine, near Cananea, was stabbed to death last week. The whole camp is now idle, only pumps at the Capote mine being at work. Colonel Calles is in command of about 800 troops.

PERSONAL

PHILIP ARGALL was in the San Juan this week.

J. W. GREGORY has gone to Australia and China.

CHARLES JANIN is expected in New York July 20.

A. S. HOWE has returned from Arizona and gone to New York.

R. E. CRANSTON has gone to Cripple Creek from New York on professional business.

WALTER N. VANCE has resigned as topographer in the United States Geological Survey.

FREDERICK G. COTTRELL has been appointed chief chemist of the United States Bureau of Mines.

E. N. BARBOT DE MARNY, of St. Petersburg, Russia, was in San Francisco on his way to Alaska.

J. D. HUBBARD, SEELEY W. MUDD, and W. Y. WESTERVELT were among San Francisco visitors Wednesday.

E. K. SOPER has returned to Minneapolis from northern Manitoba, where he has been making examinations.

COLIN FRASER, formerly on the staff of the geological survey of New Zealand, is inspecting the Mt. Morgan mine, Queensland.

J. O. HUDSON, senior inspector of mines at Kalgoorlie, Western Australia, has been appointed chief inspector of mines for Tasmania.

H. M. KINGSBURY has left the Conrey Placer Mining Co., at Ruby, Montana, to accept a position with the Kyshtim Corporation at its mines in Russia. Mr. Kingsbury left New York for London July 7.

WARREN D. SMITH has resigned as chief of the division of mines, Bureau of Science, Manila, P. I., to become head of the geological department, University of Oregon. Mr. Smith will spend the summer at Madison, Wisconsin.

GEORGE B. CHURCH has resigned his position as head of the engineering department for the Goldfield Consolidated Mines Co., after a service of more than seven years, and has accepted a similar position with the Dome Mines Company.

D. C. JACKLING returned to Salt Lake City on July 12 from Juneau and a brief stay at Butte. Mr. Jackling will be in Salt Lake City for two weeks and will then go to Chicago and again to Alaska and back to Salt Lake City by the end of August.

W. L. SAUNDERS, A. R. LEDOUX, GEORGE F. KUNZ, JOHN HAYS HAMMOND, J. F. KEMP, W. R. INGALLS, B. B. LAWRENCE, BRADLEY STOUGHTON, and E. GYBBON SPILSBURY joined in giving a luncheon at the Downtown Club in New York, July 2, to C. F. RAND, in recognition of the presentation to him of the Order of Isabella by the King of Spain.

In the Department of Geology of Northwestern University, the following appointments have been made, to take effect on September 1, 1914: JOSEPH E. POGUE, of the United States Geological Survey, to be associate professor of geology and mineralogy; WILLIAM H. HAAS, of the University of Chicago, to be instructor in geology and geography; HENRY R. ALDRICH, of the Massachusetts Institute of Technology, to be instructor in mining and metallurgy; and JOHN R. BALL, of Northwestern University, to be assistant in geology.

THE U. S. Civil Service Commission announces an open competitive examination for assistant engineer of mine tests. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Bureau of Mines, at Pittsburgh, Pennsylvania, at a salary ranging from $1800 to $2400 per year. An educational training equivalent to that required for the degree of bachelor of mining engineering from a college or university of recognized standing; at least three years' subsequent experience in testing structural materials and in computations; and two years' field work in mining, since graduation from college, are prerequisites for consideration for this position.

GEORGE D. WHITCOMB, president of the mining machinery firm that carried his name, and who died at Glendora, California, two weeks ago, was one of the pioneers in his line. He began in the coal mines, and, being of an inventive turn of mind, developed the Whitcomb pick mining machine. This led him into manufacturing, first of the pick machine itself, and later of gasoline locomotives and other machines for mine use. He built up a large business with a plant at Rochelle, Illinois. Though over 80 years of age at the time of his death and resident in another state, he retained his keen interest in the business. The active management has been for some years in the hands of his son.

SOCIETY MEETINGS

AUGUST	
American Institute of Mining Engineers, Salt Lake City	10-14
British Association, Adelaide, South Australia	8
Canadian Mining Institute, Rocky Mountain branch, Banff.	
Lake Superior Mining Institute, Ishpeming, Michigan	31 to Sept. 3
SEPTEMBER	
American Chemical Society, Montreal	15-18
American Institute of Electrical Engineers	not fixed
Colorado Scientific Society, Denver	3
Illuminating Engineering Society, Cleveland	21-25
OCTOBER	
American Institute of Electrical Engineers	9
American Iron and Steel Institute	23-24
Colorado Scientific Society, Denver	3
NOVEMBER	
American Institute of Electrical Engineers	13

American Museum of Safety	11-20
American Society of Mechanical Engineers	7-8

SCHOOLS AND SOCIETIES

LEHIGH UNIVERSITY summer school in mine surveying was held this year at Hazleton, Pennsylvania. Sixteen men took part in the work, which consisted of surveying a portion of the Wharton coal seam.

The SOUTH DAKOTA SCHOOL OF MINES, at Rapid City, has issued its *Annual Catalog*. The school year starts on September 16. There are 12 instructors in the faculty. In its 110 pages, this publication gives all details of the school and courses given.

The second INTERNATIONAL SAFETY EXPOSITION will be held in New York City, December 12 to 19 at the Grand Central Palace, under the direction of the American Museum of Safety. The purpose of the exposition is to show how the health and safety of the worker is being looked after in the various American industries, manufacturing, trades, railroading, building, business, and engineering, as well as the methods which have been adopted for the welfare and education of employees.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 16.—All metals are quiet and weak. What copper gained last week, it lost this week, prices being just the reverse. While there is a good turn-over of shares on the Stock Exchange, investors and others are holding back. In St. Louis, lead and spelter are dull at 3.75 and 4.80c. respectively. Bar silver is weak in London at 25½d. (50.5 cents) per ounce.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask

or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
June 18	38.50	July 2	38.50
" 25	38.50	" 9	37.50

REPORT of the Mine Inspector for the territory of Alaska, to the Secretary of the Interior, for the fiscal year ended June 30, 1913. P. 10. This was mentioned in this journal of June 6, 1914.

Abrasive materials consumed in the United States in 1913 were worth $4,582,949, an increase of $665,056 over 1912.

ARON HIRSCH & SOHN'S ANNUAL COPPER REPORT

This is the twenty-second annual issue of this Halberstadt, Germany, firm's 'Statistical Compilations About Copper,' and has been forwarded by L. Vogelstein & Co., its representative in New York. Production of the world in 1913 was 993,200 long tons, compared with 1,005,740 tons in 1912, from the following countries:

	Long tons		Proportion
Country.	1912.	1913.	of total, %.
United States	550,030	546,300	55.00
Japan	65,000	72,000	7.25
Spain and Portugal	58,000	53,000	5.34
Mexico	72,400	52,000	5.24
Australia	45,500	46,500	4.68
Chile	37,000	39,400	3.97
Canada	33,500	34,000	3.42
Russia	33,000	33,800	3.40
Germany	30,500	30,500	3.08
Peru	27,400	25,700	2.59
Sweden and Norway	13,600	14,000	1.41
South Africa	7,000	9,000	0.91
*Katanga	2,500	7,200	0.72
*German Southwest Africa	6,000	6,500	0.65
*Servia	6,000	6,000	0.60
Austria-Hungary	3,960	4,100	0.41
Bolivia	2,000	3,500	0.35
Italy	2,350	2,200	0.22
Turkey (estimated)	500	500	0.05
Newfoundland	1,000	.....	.....
†Miscellaneous (estimated)	8,500	7,000	0.71
Total	1,005,740	993,200	....

*Hitherto included in miscellaneous.

†Including Cuba, Venezuela, Argentina, North Africa, and Bulgaria.

The consuming countries are as follows:

Country.	1912. Long tons.	1913. Long tons.
Germany	243,173	256,566
France	106,753	107,283
England	147,551	147,434
Austra-Hungary	50,596	41,021
Russia	38,818	39,475
Italy	34,378	30,891
Belgium and Holland	13,000	13,000
Scandinavia	7,500*	8,500*
Rest of Europe	2,500*	3,000*
Total Europe	644,263	647,170
North America	365,922	342,528
Rest of America	3,000*	3,000*
Total America	368,922	345,528
China	4,000*	5,000*
Japan and rest of Asia	27,000*	32,000*
Africa and Australia	1,000*	1,700*
Total world consumption	1,045,185	1,031,398

*Estimated. Australia uses 1000 tons of its refined copper, and imported copper manufactures (no brass included) of 4906 tons in 1913 from England.

Stocks of metal at the beginning of 1913 were 55,000 tons in America and 43,101 tons in the rest of the world; and at the end of 1913, 40,822 tons in America and 29,519 tons in the rest of the world. The Hamburg Metal Exchange handled 239,250 tons compared with 252,000 tons in 1912, and 100,000 tons in 1911. The German electrical industry absorbed about 47% of that country's total Russian production included 17,280 tons from the Urals, 5651 tons from Siberia, 10,008 tons from the Caucasus, and 1375 tons from chemical works.

Monthly Copper Production

ANACONDA COPPER MINING CO., Butte, Montana. $108,312,500 in $25 shares; controlled through Amalgamated Copper Co. which owns 3,185,240 shares by Thos. F. Cole, J. D. Ryan, and Standard Oil interests; 10,000-ton concentrator and smelter at Anaconda; 5000-ton concentrator and smelter at Great Falls, Mont.; also 70-ton electrolytic refining plant at Great Falls. Production figures include copper from all companies which ship custom ore to Anaconda smelters. Total in 1913, 270,301,644 lb. copper, 64,898 oz. gold, and 10,321,296 oz. silver.

MINING DECISIONS

PERSONAL INJURY—MINE OWNERS LIABLE

A shaft boss at a mine undertook an independent contract with the mine owners to sink a shaft 300 ft. deeper. He was, however, retained on the company's payroll and his men employed on that particular piece of work were paid through the company's office. One of his men was injured and brought suit against the company. Held, that on the above statement of facts, the jury's finding that the contractor was still an employee of the company and the company liable for the injury, would not be disturbed.

Watson *v.* Hecla Mining Co. (Washington), 140 Pacific, 317. April 29, 1914.

GRUBSTAKE CONTRACT—"PROCEEDS" DEFINED

In a grubstake contract entered into in 1898, providing for a division "of all the proceeds derived from said venture," that wages earned should be treated as proceeds, and that the contract should continue so long as defendant was in Alaska, the word "proceeds" meant net proceeds, so that where the net result of the venture was that the defendant in 1903 finally returned sick and penniless, plaintiff could not recover.

Troutman *v.* Polhill (Washington), 140 Pacific, 319. April 29, 1914.

MINERAL LOCATION—REQUIREMENTS SATISFIED

A locator abandoned a portion of his claim in order to relocate another claim including the abandoned portion of the first one. He wrote his location notice on a piece of white paper, placed it on a stick, and partly covered it by a rock to prevent it from being blown away. Held, that the abandoned portion of the first claim was unlocated mineral land, open to relocation, and that the posting of the location notice in the manner indicated was a sufficient compliance with the laws of Colorado to validate the claim.

Emerson *v.* Akin (Colorado), 140 Pacific, 481. April 13, 1914.

RIGHT-OF-WAY—EFFECT OF ABANDONMENT

A person having the right to go upon another's land 'to bore and develop said land for oil and gas with the necessary, usual, and convenient rights' therefor, has a right to build a road over the land, when necessary to haul machinery and material to the place selected for drilling a well; but is liable for injury to the land resulting from the road construction if he subsequently abandons the contemplated exploration before drilling the well.

Coffindaffer *v.* Hope Natural Gas Co. (West Virginia), 81 Southeastern, 966. May 21, 1914.

MINER'S LIEN—VALIDITY UPHELD

The Nevada statute gives a right of lien to both contractors and laborers for materials furnished and work done on mining property. Held, that a joinder of a claim of lien under a contract of employment by the day with one under a contract of employment for a specified amount of work at an agreed price per foot, the work being continuous and of the same character under both contracts, would not invalidate the lien. Nor need all the parties to the contract, where under its provisions they were to be paid severally, join in the lien claim. Each may file a claim for the amount due him. Lien statutes are remedial laws and should be liberally construed.

Ferro *v.* Bargo Mining & Mill Co. (Nevada), 140 Pacific, 527. April 28, 1914.

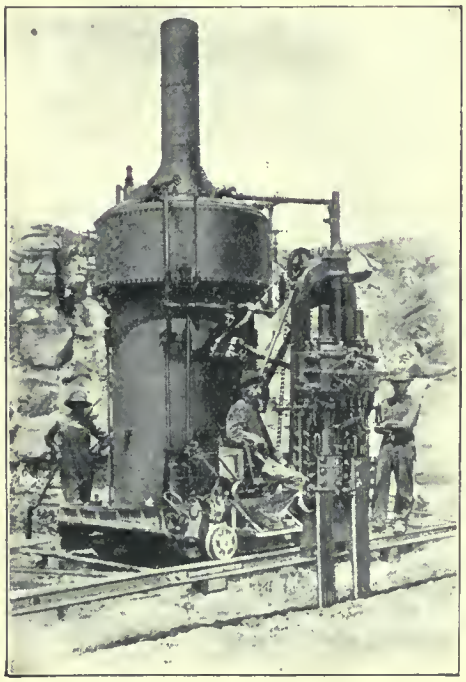
New Machines and Devices

Channeling Machines

In certain types of large excavations the channeling machine is indispensable and the popularity and field for this machine is growing as it has been found adaptable to uses other than quarrying. In excavations for cannals, locks, wheel pits, railroad cuts, the straight smooth solid wall cut by the channeler has advantages of economy and mechanical importance which render these machines as essential a part of a contractors equipment as the rock-drill or air-compressor. The channeling machine cuts exactly to the surveyed line of the work. This is difficult if not impossible, when a wall is made by drilling and blasting. In the latter case too much rock is removed at some points and the vacancy must be filled by concrete or other expensive means. A further economy which may be considered is the fact that the channeled cut affords the powder used, in blasting rock inside of the line, an additional free face upon which to act. This of course reduces the amount of powder necessary. The wall left by the channeler remains as solid as the rock strata themselves, since it is not weakened or shattered by explosives. Retaining walls to prevent rock falls or slips are also obviated by the use of this machine. The channeled walls are less affected by weather than roughly hewn, blasted sides. Channeling is also desirable when it is necessary to excavate close to the foundations of existing structures, since the ground outside of the cut is not disturbed by explosives. A recent publication entitled 'Sullivan Stone Channelers' and Bulletin 68-A issued by the Sullivan Machinery Company, of Chicago, discusses in detail the various types of machines manufactured and the wide range of uses to which they are adapted. The accompanying halftone is that of a Sullivan duplex channeler, with 8-in. cylinders, which is claimed to be the fastest cutting and most powerful channeling machine ever built.



DUPLEX CHANNELER.

Variable Volume Air-Compressor

The 3-cylinder variable volume air-compressor manufactured by the Bury Compressor Co. of Erie, Pa., represents a departure from the usual compressor design. The operation is automatic and entirely independent from any working part and in no way limits the speed of the compressor. The air supply is controlled through separate and independent variable volume unloading by-pass valves attached to each end of the two low-pressure cylinders and two similar valves on each end of the one high-pressure cylinder.

These unloading valves, it is claimed, are regulated for a close variation of 1 lb. in pressure to control the intake supply of air for full load, ¾ load, ½ load, ¼ load, or no load, to automatically meet the air requirements for any period of time. This automatic regulation stops compression by opening to atmosphere one, two, three, or four ends of the two low-pressure cylinders; and in unison with high pressure cylinder, divides the loads between the cylinders. In this manner, it is possible to regulate the peak load of compressor for any period of time.

Commercial Paragraphs

The July number of 'Leschen's Hercules,' published by the A. Leschen & Sons Rope Company, of St. Louis, Mo., contains a short discourse on the use of Hercules rope on Alaska gold dredges.

The Sullivan Machinery Co., Chicago, Illinois, has recently opened a branch office at Juneau, Alaska, which will be managed by Burt B. Brewster. The new Juneau agency has quarters in the New Brunswick building on Front street of that city.

The Denver Engineering Works Co., Denver, Colo., has recently issued Bulletin No. 1068, which is descriptive of the tube-mills manufactured by this Company. The bulletin is fully illustrated and describes the many details of construction of this type of machine.

The Chicago Pneumatic Tool Co., Chicago, Ill., has recently issued Bulletin No. 34-N., which is devoted to a description of Class 'N' steam and power-driven enclosed compressors. This type of machine has been designed for both stationary and portable use and the various sizes together with details of construction are discussed in this bulletin.

'Core Drilling by Contract' is the subject of an attractive little booklet recently issued by the Sullivan Machinery Company. The purpose of the booklet as stated in the preface is to remind engineers, mining companies, and capitalists of the facilities which the Company offers for undertaking mineral prospecting and test boring contracts of all kinds with the Sullivan Diamond core drills.

The June number of 'American Vanadium Facts,' published by the American Vanadium Company, of Pittsburgh, is devoted largely to the use of vanadium in heavy locomotives. In a series of tests which are published in this number it will be noticed that the specified minimum elastic limit for heat-treated chrome-vanadium steel is 50% higher and the minimum tensile strength 17½% higher than for heat-treated carbon steel; while the elongation in 2-in. is about the same in each case and the reduction of area from 20 to 28% higher for the vanadium steel.

SMELTING has been resumed at Chihuahua, the American Smelting & Refining Company having reopened its plant. This is a concrete evidence of faith in better conditions in Mexico, by people who know the country well.

IN these days when loans are being extended rather than paid and it has become a habit to issue new bonds to take up old ones, it is a pleasure to record the action of the American Locomotive Company in taking up from treasury funds $1,000,000 of its serial notes not due till October 1, following redemption of a similar amount in April.

HUME has written that "a government may endure for several ages though the balance of power and the balance of property do not coincide." That nature's balance cannot be disturbed without disastrous results is evidenced by a recent report from India that the campaign being waged against tigers has resulted in such an enormous increase in wild pigs that the crops have been greatly depleted. If the crop returns fail, this may well, in turn, affect the silver market.

THE political adviser of the new Chinese republic, Mr. George Morrison, in a recent interview in London states that there are plenty of evidences of stability in Chinese public life and finances at the present. Revolutionary activity and the operations of bandits are confined to a small area, and the £15,000,000 which was horded in the banks of the treaty ports is returning to circulation. This optimistic view of one so intimate with Chinese affairs is encouraging in light of the many rumors of incipient revolution and political unrest.

THAT flotation can be profitably applied to the treatment of the low-grade porphyry deposits appears to be the opinion of those who are engaged in this metallurgical problem. It is probable that flotation will be adopted as an auxiliary method of treatment, but not entirely to replace the present method of concentration at the Utah Copper Company's mills, according to a recent statement of managing director Mr. D. C. Jackling. The importance of the subject is apparent when it is understood that the $20,000,000 output of this Company represents an extraction of only about 70 per cent of the copper content of the Utah ores and with the flotation process it is expected to save from 85 to 95 per cent of the copper.

CONSOLIDATION of the United Mine Workers and the Western Federation of Miners is being given serious attention by these organizations at the biennial convention of the Western Federation at Denver. It is to be noted that in a report by Mr. Charles H. Moyer opposition is offered to the proposed amendment to the constitution of the Federation whereby any member who has held office for two consecutive terms is ineligible for reëlection. Although this attempt to oust the present officers of the Western Federation may not prove successful, it is evidence of a growing feeling of dissatisfaction among the better element of the organization and would indicate that the revolt at Butte was but the crystallization of this sentiment in one locality.

A MOST interesting program is promised those who attend the Salt Lake meeting of the American Institute of Mining Engineers to be held from August 10 to 14 inclusive. The program includes many features of both a technical and social nature, among which are visits to Bingham cañon, the Magna and Arthur mills, and the Garfield, Murray, Midvale, and Tooele smelters. Excursions to Park City, the Tintic mining district, and Cottonwood cañon have also been arranged. Technical sessions will be held on the evenings of August 10, 11, 12, and the morning of the 13th. At these sessions a wide variety of subjects will be discussed, particular attention being given to the metallurgy of copper, lead, and zinc. Mining methods and practice will also be treated in papers dealing with some of the problems of modern mining. The technical sessions will be held at the Hotel Utah and a most successful meeting is anticipated.

CONCESSIONS in the Arequipa borax fields will be asked for by the Borax Consolidated, Ltd., at the next session of the Peruvian congress which convenes on July 28. In that the support of the Peruvian government has been pledged and the measure was approved by the Chamber of Deputies at its last session, it is very probable that the privileges asked for will be granted. The present holdings of the Company represent an original investment of £150,000 for the property rights, and it is estimated that an additional investment of £200,000 will be required to equip the fields for production. As the working of these deposits will require a force of several thousand men and economic conditions in the Department of Arequipa have been depressed for a long

time, it is hoped locally that the concession will be granted. Under its terms the Company is to construct a railway or tramway from the borax and salt mines of Moquegua to the city of Arequipa; furnaces with an annual capacity of 40,000 tons of borax and lime are to be erected: only Peruvian workmen will be employed at the works; and the Company will spend £200,000 on the works for which this concession treats. Congress will be asked not to levy duty on the exportation of borax from the port of Mollendo for 18 years, and the municipalities not to tax borax for this period. All machinery and supplies for this work are to be admitted free of duty.

TONOPAH has been recently the scene of operation by agitators of the I. W. W. organization. One man lost his life, a boarding house was looted, and destruction of property and other acts of violence were openly preached. There is a general feeling that the peace officers failed in their duty, but the situation has its bright side in the prompt action of organized labor in the district in repudiating the trouble makers. When a systematic effort is being made, as now, to provoke open defiance of the law, a grave situation is created. The first impulse is to stand the agitators up and shoot them, but so simple a solution is not likely to be final. We have no panacea to urge, but we do feel keenly that American institutions have sufficient stability to withstand the attack now being made and that a way out can and will be found.

PETROLEUM producers should be keenly interested in events at Washington these days, as a determined effort is being made to find a solution of the various legal difficulties that have grown out of the different land withdrawals, the pipe-line legislation, and the Southern Pacific litigation. It was supposed some weeks ago that a *modus operandi* had been found whereby operators on land in dispute with the Government might have the option of accepting a lease or by depositing with the court an agreed portion of the receipts, be free to produce and sell pending settlement of the legal points involved. Bills covering these points have been framed and were expected to go through without opposition. Dispatches of this week indicate a hitch in the program. Funds, too, for the petroleum division of the Bureau of Mines that we discussed July 4, are in jeopardy, and it will take prompt and emphatic action of the oil men if money is to be available for doing the work outlined. This is particularly important, since, however much we may differ as to the propriety of the Government occupying so large a field in petroleum matters, there can be no disagreement as to the need of its action being informed. Oil men are not afraid of legislation or court decisions that are based upon real knowledge of the industry; it is half knowledge in high places that is dangerous, and in their own protection the oil men should help Mr. Williams and his associates to get the new division on a sound basis.

NATOMAS FINANCES AGAIN

Our criticism of the plan of reorganization of Natomas Consolidated has provoked comment from many sources. It, and the general discussion of the matter, has served the excellent purpose of bringing out additional information, so that bondholders and others may more intelligently decide upon a course of action. While a revised list of current liabilities and quick assets, compiled by Mr. Emery Oliver, general manager for the Company, was made public July 10, the general figures already presented remain substantially unchallenged. Mr. Oliver's figures do, however, permit the matter to be viewed from a different angle. He lists the outstanding underlying bonds, consisting of the unretired bonds of Natoma Development Company, Natoma Land & Milling Company, and the Clarke & Cox Farms Company as amounting to $843,000. He further states that the total amount, with interest, now owing for lands purchased but not wholly paid for, is $489,024. From an accompanying opinion by Messrs. Pillsbury, Madison & Sutro, it is learned that the floating debt, exclusive of the amount due the Natomas Syndicate, is now $815,000, and the claim of the latter, prior to return of a block of reclamation bonds, was $1,213,000. The last transfer mentioned may be disregarded, since under the proposed reorganization it would be, in effect, cancelled. Adding these various obligations, it appears that Natomas owes $3,363,024—provision for which sum must be made before the so-called first mortgage bondholders can hope to realize upon their investment. The reclamation bonds, now amounting to something over a million dollars, are purposely omitted in the above calculations, since they either are now in the treasury of the Company or would be returned to it in event of the debts above outlined being paid. In addition, however, to the $3,363,000, provision must needs be made for completing the reclamation work and for interest charges. There is equity back of all these debts and, what is at least quite as much to the point, the creditors, in the main, have such security in the form of liens, cash, or underlying bonds as put them in a strategic position. Settlement must be made with them, or the bondholders will lose the property. The debts must, and ought to be paid. The question is the purely practical one of how they may be best met.

Not all the money needs be paid at once. For example, but $100,000 of the Natoma Development Company bonds falls due this year. Mr. Oliver lists obligations to the amount of $1,332,226, including $554,361 for the minimum of reclamation work, that must be met by January 1, 1915. He also estimates $803,000 as the income for the remaining months of the year. These are hard facts that must be met by any plan for reorganization and in urging caution on the part of bondholders, we have had no intention of suggesting repudiation of any debt.

Repudiation is one thing, however, and the price paid for money borrowed is another. Under the plan pro-

posed, Natomas Syndicate will pay $2,700,000 for notes worth $3,000,000. From this the Syndicate will, directly or by underwriting, care for a floating debt of $818,000 and its own debt of $1,213,000, so that the new money contributed will amount to $670,000. The payment of the floating debt will, however, release cash now held in banks, so that, as Messrs. Pillsbury, Madison & Sutro say, $1,000,000 cash will be available for use. Furthermore, since payment of current accounts will naturally extend local credits, the effective sum will be even larger. Interest and sinking fund to retire the 6 per cent notes in the five years will add an annual charge for that time, though interest on the first mortgage bonds will be allowed to accumulate. The plan may well, as its friends hope, clear away the present difficulties and eventually bring the bondholders more than the present value of their bonds. At the same time, it is true that, disregarding the new stock, which is of problematic value, the bondholders are scaled down to 60 per cent of their holdings and wait for their interest, while Natomas Syndicate will get full value for its advances, plus 6 per cent interest, and a commission on the money advanced. In case the notes are not paid within the five years, the Syndicate will also receive $4,500,000 out of the new issue of $16,500,000 bonds. The practical question is whether this is the best bargain that can now be made.

It must be remembered that Natomas Syndicate, and other of the creditors, have in their possession underlying securities which in any scramble would protect them and take the whole property. Whether such securities should have been pledged is beside the question. They were—and to raise money with which to pay interest to bondholders. If there was benefit from the transaction the latter secured it. It is also worth remembering that an appeal to the courts and a receivership would probably depreciate the property so greatly, since the reclamation work is incomplete and there are so many interests to be reconciled, that no one would be the gainer. Whatever else may be done, we hope that the present sensible and economical policy of amicable readjustment with expenditure upon works rather than lawsuits, will be followed. In fact, we believe the bondholders will best serve their own interests by joining with the reorganization committee, and working substantially along the lines proposed.

When we wrote of the subject a month ago we had in mind the possibility of a group of the bondholders offering an alternative proposal or working together to secure modification of the terms of the Natomas Syndicate. No adequate proposal of this sort has been made, and under the circumstances we would strongly urge all bondholders to accept the situation and come in on the plan offered. Any terms are better than a prolonged contest in the courts, and quick action is necessary. The management must stop the reclamation work unless the project be financed within the next few weeks, and if the half-finished levees be exposed to the probable floods of the winter, much of the value of the work already done will be lost. Even if the work were resumed a year later, the mere loss of time, because of interest charges, would have added $10 or more to the cost per acre of the land. From this point of view the commission paid Natomas Syndicate is less important than the protection of the work.

It is to be remembered that the bondholders have never had a perfect first lien on the property. The underlying bonds of the constituent concerns and the reclamation bonds have precedence. The latter, it is true, were in the treasury of the Company until pledged as security for loans and later sold to the Natomas Syndicate. The plan of reorganization proposes that they be returned, and we would respectfully suggest that they should not be allowed to be again pledged. Otherwise, if the notes are not paid, the end of the period will find the old bondholders with about two-thirds of the outstanding bonds, 40 per cent of the preferred stock only, practically none of the common, the unpaid notes, and the best of the gold land dredged. It is true this is a matter of management, and the new board that is proposed is one of the best guarantees possible that everything will be done to make things go well. It is none the less a vital matter to the bondholders and should receive attention.

One other matter we may venture to suggest. If any reliance is to be placed upon the estimates available, the gold reserve in the dredging ground has a present cash value considerably in excess of all the debts of the Company, and, if the dredging lands could be sold for their cash value or nearly it, all debts could be wiped out and a surplus would be available for reclamation work at least equal to, and probably greater than, that provided by the reorganization plan. In the end the bondholders must save their capital and take their profit, if any, from the sale of the reclaimed land, and, while the new Natomas may be able to conduct gold-dredging as economically as any other concern, it must in the meantime pay more for money. In other words, future profits are worth less and present cash is worth more to Natomas than to others prepared to dredge. We believe that, properly presented, there would be lively bidding for the dredging lands, but for the directors to propose to sell the property most immediately valuable would subject them to criticism. An outsider, such as ourselves, may properly offer the suggestion. It would be entirely possible to reserve the right to do this if found practicable. Natomas bondholders can hardly expect to have their cake and eat it, too. It is a choice of evils they must face. Let them do it frankly. We have no quarrel with Natomas Syndicate or the present committee. They are making an effort, deserving of success, to avoid a receivership. They should have the coöperation of the bondholders, and if the latter will not face debts that must be paid, they can hardly expect to escape loss.

Siderite and Sulphides in Leadville Ore Deposits—II

By PHILIP ARGALL

The derivation of vein siderite at Leadville may be from the slaty and thin bedded Silurian limestones or from the porphyries, but without doubt it is derived from the rocks traversed by the mineralized solutions that in their passage through the fissured rocks formed the vein and replacement deposits. It is significant that some of the gray porphyries on mine dumps are in a few years covered with a heavy film of black oxide derived from their manganese content; proving that some Leadville porphyry contains manganese in appreciable quantity, that oxidizes somewhat readily under atmospheric conditions. Emmons, in his Leadville monograph,[1] gives two analyses of comparatively fresh gray porphyry containing 0.0677% manganese, equal to one and one-third pounds per ton of rock.

Spurr and Garrey, in their discussion of the gangue minerals of the Georgetown quadrangle,[2] claim that siderite may be derived from original pyrite, "as is probably the case in one instance noted in the Harrisburg mine, where a post-mineral fissure had been opened in

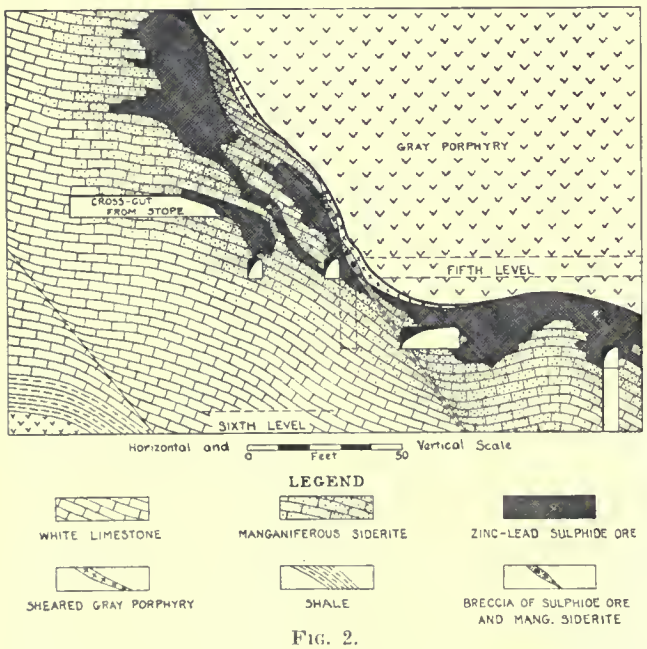

FIG. 2.

pyritic altered rock and had become lined with siderite that was evidently due to lateral secretion." They also state that when siderite occurs as a primary mineral or as the last formed mineral, it is usually mingled with other carbonates; especially that of manganese. Siderite is thus contemporaneous with primary pyrite and "its iron, like that of the pyrite, has probably been derived from the rocks traversed by the mineralizing solutions. This conclusion applies also to the manganese in the brown carbonates." Elsewhere these authors state that siderite or ankerite in the Colorado Central mine, represents "the crystallization along the walls of cavities of the carbonates abundantly formed by alteration of the biotite and feldspar of the wall rock."

The latter hypothesis is entirely inadequate to account for the Leadville replacements, nor can I conceive of iron sulphide being converted into carbonates on a scale commensurate with the Leadville deposits. In various places in the Tueson mine the beds of siderite are of such wide extent as to suggest sedimentary deposition. Observing a drift closely following the strike of the beds in such locality, samples were taken at intervals of 20 ft. along one particular bed and assayed with the following result:

Sample.	From fissure, ft.	Iron.	Manganese.	CaO.	Insoluble.
		%	%	%	%
A	40	24.3	16.2	1.8	16.6
B	60	5.2	3.1	19.6	25.2
C	80	3.4	1.2	24.1	13.2

A second place was chosen where ore was mined along a 'flat' in the foot-wall country of a fissure where, on reaching the limits of pay-ore, a cross-cut had been extended through the siderite into the unreplaced limestone following the bedding. Samples here gave the following results:

Sample.	Ft.		Iron.	Manganese.	CaO.	Insoluble.
			%	%	%	%
A	10	from ore	26.6	18.9	0.6	29.6
B	20	from ore	19.4	21.0	0.7	19.2
C	30	from ore	16.7	20.1	1.2	25.0
D	40	from face of cut top ...	4.2	3.2	19.6	20.0
E	40	from ore-floor of cross-cut	3.6	2.8	23.0	18.0

These samples conclusively showed that practically complete siderite replacement of the limestone extended 30 ft. beyond the termination of the zinc-lead ore (see Fig. 2, cross-cut from stope) extending as a 'flat' from the fissure, and then gradually faded out in 10 ft., as shown in samples *D* and *E*. In fact, the change in the cross-cut is so gradual and imperceptible that no person with the unaided eye could determine in the mine the limestone from the siderite; or say between the rock represented by samples *C* and *D*. Consequently the siderite has, perhaps, been mistaken for white limestone, both by the miners and by the visiting scientists. To the former siderite was waste or gangue containing neither precious metals, zinc, nor lead in paying quantities, so he had no use for it. These tests, together with other observations, prove to my satisfaction that the siderite beds and included orebodies are replacement deposits; and, inasmuch as the physical conditions—that is, the adjacent porphyry mass, the contact-

[1] U. S. Geol. Surv., 1886, p. 332.

[2] U. S. Geol. Surv., Prof. Paper 68 (1908), p. 153.

metamorphic minerals in the limestone, and the presence of siderite in the intrusive gray porphyry sheet itself—suggest that the ores were derived from magmatic solutions and vapors emanating directly from the intrusive mass of gray porphyry, I am led to the conclusion that this is a contact-metamorphic deposit of great significance in the study of the genesis of Leadville ores.

In his last contribution to the geology of Leadville, S. F. Emmons, writing of the ultimate source of the metals, states:[3] "The questions still at issue are:

"1. Whether the sulphide ores were originally deposited as a precipitate exclusively from meteoric or from magmatic waters, or in part from both.

"2. Whether the magmatic waters, if they were the transporting agents, reached the present locus of the depths directly from below, or whether they came up along the general channels that carried the magma of the intrusive rocks, and, where this magma had spread out in sheets between the sedimentary strata, whether they followed in general the contacts between intrusives and sedimentaries or penetrated the mass of the latter along cracks and joints before depositing their load.

"3. Whether the deposits, or any part of them, were formed by contact metamorphism—that is, by waters emanating directly from the cooling intrusive bodies, squeezed out, as it were, from the solidifying igneous mass into the adjoining sedimentary beds."

I believe that the section, Fig. 2, answers the first and last questions in favor of magmatic waters and of contact metamorphism. It also throws much light on question No. 2. The gray porphyry shown in Fig. 2 is the eastern edge of the huge sheet exceeding 200 ft. in thickness extending over the greater part of the Tucson claim. The folding and fissuring is coincident with the porphyry intrusion, but the slight fissuring shown in this illustration had, I believe, little to do with the ore deposition, though movement has occurred along the fissure nearest the porphyry since the formation of the replacement deposit and some ore breccia was developed along its plane. In support of the contact-metamorphic theory of deposition for the orebody illustrated by Fig. 2, I call attention:

1. To the silicification of the limestone by means of what I take to be emanations from the intrusive porphyry. I have previously noted the silicious nature of the siderite, averaging in samples *A*, *B*, and *C* 24.6% insoluble. Taking these samples as representing siderite, and *D* and *E* the silicified limestone, the following comparison may be made:

	Iron.	Manganese.	CaO.	Insoluble.
	%	%	%	%
Siderite	20.9	20.0	0.8	24.6
Limestone	3.9	3.0	21.3	19.0

Inasmuch as wollastonite had been noted in other portions of the deposit, lime silicates were suspected here, and two slides were prepared which revealed nothing but quartz in the limestone at 80 ft. from the porphyry, where the temperature was evidently not high enough to form lime silicates.

2. To the massive siderite itself, which I consider a metamorphic mineral deposited simultaneously with the mixed sulphides, including pyrite and pyrrhotite, also specular hematite and magnetite.

3. To the chloritic material adjoining the porphyry which may be derived in part from the decomposition of pyroxene.

4. To magnetite bands (one 12 in. thick) associated with hematite, considerable of which is of the specular variety, and to pyrite bands, in part pyrrhotite, alternating with siderite and zinc-lead sulphides.

Finally, the minerals appear to be derived from the same source and deposited about the same time, the zinc-lead sulphides forming in masses near the porphyry, the massive siderite next, and the silicification of the limestone extending as the outer border of metamorphism. The siderite, and to lesser extent the silicified limestone, contains much sulphide material in scattered crystals throughout the zones indicated; that is to say, distinct crystals of galena, sphalerite, and pyrite, apparently segregated from the siderite mass.

On these facts I base my conclusion that the section Fig. 2 illustrates a contact-metamorphic ore deposit.

The Tucson Fault-Fissure

The siderite deposited in the Tucson fault-fissure and replacements therefrom may have had a deep-seated origin, or the iron and manganese may have been derived from the Silurian limestones, but inasmuch as the development of this fissure vein is not by any means extensive, the ultimate source of its siderite may eventually be traced to the porphyries.

It is noteworthy that the siderite veins briefly described in this paper occur in the older sedimentaries:

Perran Iron Iode	in clay slates	Lower Devonian
Brendon Hills	in clay slates	Middle Devonian
Stahlberg Musen	in clay slates	Lower Devonian
Slocan mine	in clay slates	Pre-Cambrian
Coeur d'Alene	quartzite	Pre-Cambrian
Leadville	quartzite and limestone	Cambrian and Silurian

Composition of Leadville Siderite

The following analyses were made on selected specimens from the Tucson mine, fairly free from sulphides, but containing minute specks of galena, pyrite, and zinc-blende. For part chemical analysis of siderite from other Leadville localities, see preceding table:

	A.*	B.*		A.*	B.*
	%	%		%	%
Iron	23.07	21.80	Lead	1.50	0.60
Manganese	20.70	21.10	Zinc	0.30	0.30
CaO	0.30	0.40	Gold, oz.	0.04	0.04
Insoluble	19.60	21.20	Silver, oz.	0.08	0.00
MgO	1.40	2.40			

*P. T. Gallaher, analyst.

[3] 'The Downtown District of Leadville, Colorado,' *Bull.* 320, U. S. Geol. Surv., 1907, p. 72.

The small quantity of lead, zinc, and silver present in the siderite is accounted for by the scattered crystals of galena and blende impossible to separate. The gold is as high in the siderite as in the sulphide ore, and to account for it is difficult; apart from this metal, the siderite is apparently free from combined zinc, lead, and silver, and may be considered a true gangue.

Structure

Probably the best development of siderite in Leadville today can be seen in the Tucson mine; at any rate, it is the occurrence with which I am most familiar, inasmuch as I recently examined the mine.

The Tucson has three important structural characteristics: (1) steeply folded beds approaching a thrust, reverse, fault of about 200 ft. throw, which brought the Cambrian quartzite of the hanging country above the white limestone of the foot; (2) an immense sheet of gray porphyry exceeding 200 ft. in thickness intruded below the parting quartzite; (3) the development of shearing in the foot and hanging wall country paralleling the fault and the deposition of ore therein. These structural peculiarities greatly complicated mining development. The shaft passed twice through the white limestone and Cambrian quartzite and first struck rich ore in the foot-wall quartzite on the 9th level, close to the granite. This ore has since been followed upward along the quartzite bedding planes for a distance of 600 ft. from the granite quartzite contact. Through these structural peculiarities the mine has been worked from the bottom up. The 9th and 10th levels are today under water, while the 5th and 4th levels are only now being developed.

The Tucson fault has been followed from 40 ft. below the granite-Cambrian contact to 60 ft. into the 'blue limestone' a vertical height of 600 ft. measured in the foot-wall formation. On its strike the fault has been traced a length of 1500 ft. No record of the fault is found on the old maps of the 'first contact' workings, the 'white porphyry'-'blue limestone' contact exhausted of carbonate ore and abandoned over 20 years ago, so it is highly probable that the Tucson fault flattened out into a bedded fault in the 'blue limestone' and became dissipated in the bedding planes below the 'first contact' horizon.

The age of the Tucson fault is not easily determined, for the reason that present development has not been sufficient to fully prove up all the geologic conditions; particularly in the hanging wall country and in the 'blue limestone' horizon, while the steeply folded beds and the intrusive sheet of gray porphyry adds to the complication. The fault and attendant shearing appear to have been coincident with the porphyry intrusion and earlier than the ore deposition in the Cambrian and Silurian horizon. The quartzite ores are certainly subsequent to the faulting as are also the siderite replacement deposits and accompanying zinc-lead ores. The fault in places becomes a typical fissure vein filled with alternating bands of leaded zinc ore and siderite. The normal faulting in Leadville took place after the formation of the sulphide replacement deposits of the blue limestone-white porphyry ('first contact') horizon. The Tucson fault, if I read the evidence correctly, preceded the ore deposition in at least the lower sedimentaries and is older than the normal Leadville faulting, such as the 'Iron fault' for example.

Ore Deposits

The quartzite ore deposits are found along the shearing planes as lining in solution cavities, along some bedding planes, and on the bottom and to a less extent on the roof and sides of irregular horizontal solution cavities or 'water courses.' The richest ore in the Tucson mine was found between the 9th and 10th levels; as well as the largest solution cavities, exhibiting the most intense action on the quartzite. Some of the crusted ore near the bottom of cavities on this horizon assayed 14 oz. gold per ton, 4000 oz. silver, and 45% lead; antimony and bismuth minerals are also present.[4]

The photographs reproduced as Fig. 3 and Fig. 4 illustrate the peculiar deposition.

Fig. 3 shows an ore occurrence in Cambrian quartzite above the 8th level. The ore can be clearly seen partly filling an oval solution cavity (water-course) between tight shearing planes in the quartzite. One such is marked by the pick and the other indicated by the drill-hole at the top of the picture. The ore is a mixed sulphide covered with fine crystals of siderite. This figure is offered as an example of a typical high-grade deposit of what I shall call the 'Red Cliff type', for the reason that at Red Cliff similar channels or water courses, following tight shearing planes or cracks in the quartzite and in places spread out along bedding planes, have been worked for many years, often at great profit. The Eagle river at Red Cliff has cut through the sedimentaries and deep into the granite, exposing many veins and some replacement deposits in the precipitous cliffs, which latter carry oxidized ores to considerable depth into Battle mountain, along the dip of the quartzite beds. Some of the quartzite ore channels produced magnificent specimens of crystalline gold and much gold and silver ore of high value.[5] It is evident these channels, incipient fissures, and bedding planes, favorable to the passage of mineralizing solutions, were in part filled with rich ores, the oxidation of which in moist condition or in stagnant pools produced the crystalline gold noted above. The Leadville ore illustrated in Fig. 4 assayed: gold, 0.38 oz.; silver, 610.8 oz.; lead, 37.2%; copper, 0.7%; zinc, 24.6%; iron, 6.8%; insoluble, 4.6%. Such ore should, on oxidation under like conditions, produce metals and minerals similar to those of Red Cliff; hence these rich quartzite ores are common to both mining districts and elsewhere in Colorado, though but recently recognized in Leadville. The primary quartzite ore in the Tucson is much richer than that found in the limestone; furthermore, it decreases in gold and silver content and increases in copper (chalcopyrite) as followed upward along and through the beds. The deposit sometimes fades out on one bedding plane, rising through a fissure or solution cavity and continuing on a higher plane, being often enriched by incipient fissures. The cause of the varying richness of the ores in quartzite and in limestone and

[4]Argall, G. O., *Eng. & Min. Jour.*, Jan. 29, 1910, p. 264.

[5]Argall, Philip, *Trans.* Amer. Inst. Min. Eng., Vol. 22 (1893), pp. 759-760.

between the upper and lower beds in the Cambrian quartzite itself, is somewhat puzzling. I can only ascribe it to lack of a precipitating medium in the quartzite, rather than a change in the composition of the mineralizing solution. Be that as it may, the conditions may be tentatively stated as follows: The ascending hot solutions dissolved quartzite readily in the bottom beds, at the same time depositing sparingly in the solution cavities, partly as replacement and partly as crusted deposits, sulphides of iron, lead, copper, and zinc with much gold and silver and a little bismuth and antimonial minerals, which are comparatively rare in Leadville; then, as the solutions in their upward passages through the quartzite took up more silica their solvent action became less, the resulting cavities and quartzite replacements smaller, and the sulphide deposition heavier, resulting in filling the smaller cavities and cracks completely, chalcopyrite predominating in places; at the same time the content of precious metals in the ore fell off very considerably. So far as the precious metals are concerned, it appears not unlike a case of fractional precipitation. A typical shipment of ore from the present working faces in the quartzite is as follows: gold, 0.11 oz.; silver, 164.4 oz.; lead, 7.5%; copper, 1.15%; zinc, 7.5%; iron, 8.4%; insoluble, 57.6%. Inasmuch as there is over 50% silica present, because of the fine dissemination of the ore through the quartzite, it is manifest that the pure ore is at least double the value stated.

Fig. 3.

Fig. 4, a small fissure, *F*, in glassy quartzite, bifurcating near the middle of the picture and the branch fissures apparently closing up toward the bottom of the drift. The ore is less than two inches wide, though worth over $150 per ton. The fissure shown here runs east and west. Those in Fig. 3 parallel the fault and are the real mineralizing fissures for the bedded deposits in the Cambrian. Vugs and solution cavities at this horizon contain siderite crystals in the partly dissolved quartzite throughout the ore, and as a vigorous growth of crystals forming the final mineral deposition often covered with sericite mud which represents the softened matrix of the quartz grains. Present development has revealed but one rather narrow channel of quartzite ore in the Tucson mine.

Fig. 4.

Limestone Ores.—The largest siderite veins and replacements in the Tucson mine occur in the 'white limestone' beds at some distance from the main Tucson fault or fissure vein, and, so far as present developments show, in the folded and sheared foot-wall country. Mr. Calkins' remarks on the Coeur d'Alene deposits apply here: "Although siderite has a much wider distribution than the ores, yet it is more abundant where the rocks have been folded and fissured." To this I add, to cover Leadville occurrence, *adjacent to porphyry intrusions.* Very often one wall of a fissure deposit is found to be gray porphyry, while practically the whole siderite development in the limestone to date occurs

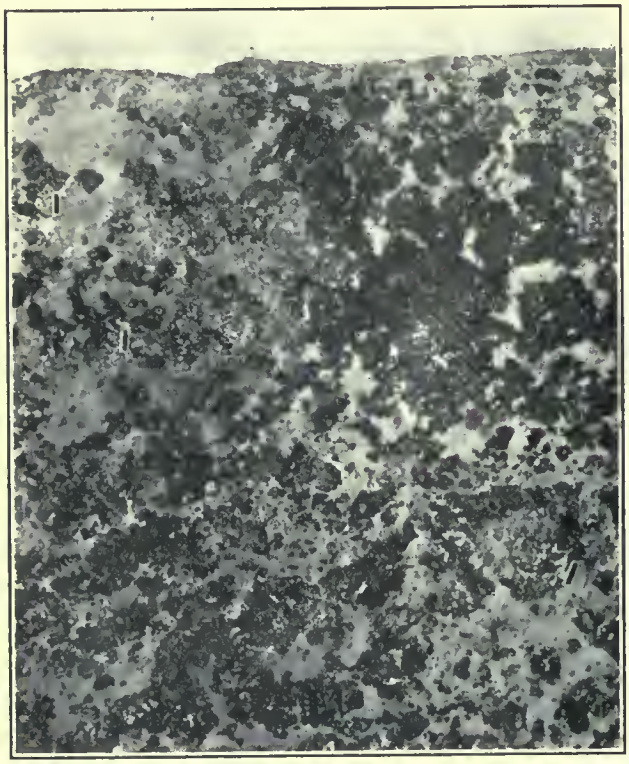

FIG. 5.

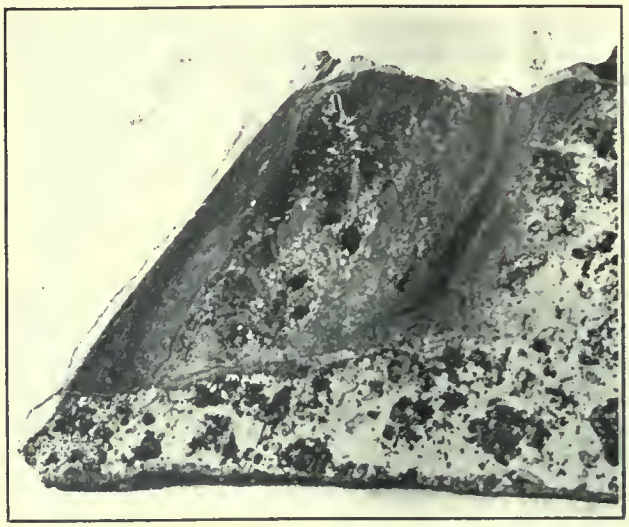

FIG. 6.

FIG. 7.

below the great sheet of intrusive gray porphyry previously mentioned. Occasionally the zinc-lead ores form on a porphyry wall, but more often a band of solid siderite adjoins the porphyry. Again, it may be slaty limestone crushed, contorted, and partly chloritic. As a rule, the zinc-lead ore occurs free from gangue or other contamination, not even intermixed with siderite. Such ore is broken down separately, the waste sorted out at surface, and the ore shipped for pigment manufacture. This zinc-lead ore, an intimate mixture of zincblende, galena, and pyrite in lesses quantity, low in silver, and of fine steel-like fracture, is not common in Leadville. It is of the variety first called 'blue stone'

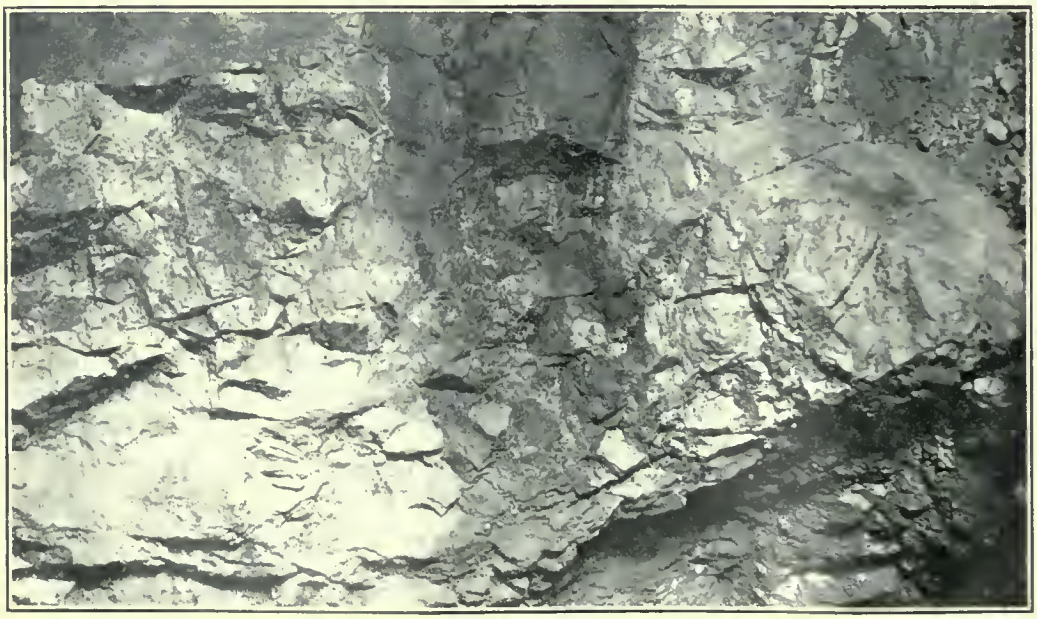

FIG. 8.

ore in Pary's Mountain mine, Anglesea, Wales, and later found in some quantity in the Ovoca mines, Ireland.[6] A similar ore occurs as a quartzite replacement in the Sullivan mine near Cranbrook, British Columbia.[7]

The Tucson zinc-lead ore is of somewhat coarser grain than the 'blue stones' referred to, yet I have not noticed coarse crystalline galena in any of the Tucson siderite repacement ores in the Silurian limestone, while invariably coarse crystalline galena is the more common form in the blue limestone 'first contact' replacement deposits. It is noteworthy that while in the orebody the zincblende and galena minerals are intimately mixed, yet in the massive siderite they occur as disseminated crystals of apparently pure minerals.

FIG. 9.

Toward the edges of the zinc-lead replacement deposits both pyrite and siderite sometimes occur as shown in Fig. 5; the dark mineral is zinc-lead; the dull white, siderite; the scattered clear white pyrite (I), which is somewhat abundant near top left-hand corner. The specimen is from 5th level, Tucson mine, enlarged two diameters. The fissure shows evidence of reopening and of considerable movement, breccia is common, and striæ and slickensides are abundant, as is also slaty limestone developing chloritic minerals and but partly replaced.

Fig. 6 is a typical example of brecciated ore. The main piece shows at the bottom and right zinc-lead ore in siderite gangue. The piece at the left, molded into position by pressure, is slaty limestone, highly silicious and partly replaced. The black is zinc-lead ore surrounded by siderite. The bright white near the top at the left-hand corner (1) is pyrite. Separating this rock from the larger is a seam of chloritic shale, which also forms the outer, left-hand edge of the specimen. Magnetite is common. A little hematite and specularite is also found in close relation with siderite.

FIG. 10.

Fig. 7 is a very instructive specimen. A small veinlet of siderite (white) is shown in a gangue of magnetite. The left side is magnetite and sandy hematite, while the right is chiefly magnetite through which fine pyrite is scattered. The white spots at the right of the siderite veinlet (1) are pyrite. A similar specimen cut and polished showed under the microscope an independent and apparently simultaneous growth of siderite and magnetite; also some specular hematite. The outline of the minerals is clear and the edges free from alteration.

Fig. 8 illustrates an occurrence of massive siderite in the white limestone, the same being the contact-metamorphic deposit shown in section in Fig. 2. The view was taken on the 5th level, P drift. The black, lower right-hand corner, is zinc-lead ore; the rest is massive siderite with a streak of low-grade ore running through it. The geology of this contact-

[6]Argall, P., *Sci. Proc.* Royal Dublin Soc., 1879, p. 225.
[7]Argall, P., 'Report of Zinc Commission,' cited, p. 230.

metamorphic replacement of white limestone is clearly shown in Fig. 2, a cross-section made by Frank A. Aicher, surveyor for the Iron Silver Mining Co. The section follows the stoping quite closely, the faces mostly representing the limit of profitable ore rather than that of zinc-lead replacement, the irregular outline of which could not be clearly shown on the small scale adopted. The orebodies are practically enclosed in vein siderite which gradually merges into the limestone, fading away at about 80 ft. from the porphyry. The siderite carries about 18% silica, and silicification of the limestone extends for over 100 ft. from the porphyry intrusion, indicating a highly silicious emanation of moderate temperature.

The source of the 'black iron' of Leadville, or rather of its manganese content, has long been a subject of discussion. I have elsewhere traced the source to the siderite bordering the orebodies.[8] When it is considered that the great mass of siderite underlying the zinc-lead ore shown in Fig. 2 will assay about 22% iron and 18% manganese, the source of the oxidized 'black iron' of Leadville is placed beyond reasonable doubt. The siderite replacement deposits in bedded form or extending out from fissures as 'flats' are extensive in the Tucson mine, sometimes carrying pay-ore, over 60 ft. from the fault fissure and siderite replacement of limestone to 100 feet.

Fig. 9 is a view in a stope 100 ft. above the 5th level. It clearly shows the arrangement of the ores. A peculiarity of these siderite replacements in the white limestone is the presence of chalcedony and whitish chert bands in the ore. Flints have apparently been dissolved and redeposited or partly dissolved and included in amorphous quartz. In Fig. 9 the chalcedony bands follow the original bedding; *c* is chalcedony, *o* zinc-lead ore, *s* siderite.

Fig. 10 shows a pillar left in an old working ('Highline' stope) about midway between the 4th and 5th levels. The chalcedony *c* is segregated. The roof is a bed of siderite, *s*, freely sprinkled with galena and blende in distinct crystals of high assay value. The pay ore *o* is mixed zinc-lead previously described. A candle is shown on a small chalcedony lens of great purity. A seem of pyrite *p* is marked by the pick and extends to the lowest visible bedding plane. I consider Fig. 9 and 10 splendid examples of limestone replacement, showing alternating beds (Fig. 10) of pyrite, of siderite slightly ore bearing, of zinc-lead ore with included chalcedony lenses, and a smooth bedding plane for the roof. The pay-ore is small but ample to illustrate the manner of deposition.

FIG. 11.

FIG. 12.

Fig. 11 is the face of a drift in a siderite replacement. The beds here are massive and quite hard. From the top of pick to the roof is solid steel-grained zinc-lead ore. From the same point to the floor, is massive fine-grained siderite, oxidized on faces and stained yellow. The white patches represent crystalline siderite enclosing zinc-lead ore (black). This drift is just entering the pay-ore after penetrating siderite beds for about 50 ft. The Tucson fault is about 50 ft. to the right.

[8] *The Mining Magazine*, April 1914, p. 287.

Fig. 12, from the 4th level, Tucson, shows a brecciated vein mostly crushed zinc-lead ore, cemented by siderite. This brecciated ore occurs in the blue limestone 15 ft. above the parting quartzite and on the foot-wall side of the Tucson fault, or fissure vein, the hanging is a sheeted zone of slaty limestone, seamed with fault clay containing breccia and pebbles of hard limestone and quartzite with occasional pieces of zinc-lead ore and much decomposed porphyry.

From about 30 ft. below the 4th level to 50 ft. above (the present extent of these stopes) the Tucson fault is a typical fissure vein, exhibiting alternating bands of zinc-lead ore and siderite as replacement of the foot-wall limestones, both the white and the blue formation. Fault clay forms the hanging wall with a sheeted zone of clay seams, shaly limestone, and decomposed porphyry extending 10 to 30 ft. into the hanging wall country. In places the vein is brecciated, Fig. 12 showing movement after ore was deposited. The fault is still moving. At other points thin beds of hanging wall limestone have been drawn into the fault zone, folded, crushed, and replaced, wholly or in part, with zinc-lead ore and again folded or fractured by further movement and pressure.

The Tucson fault fissure is not continuously mineralized. It is barren where talcy clays predominate as filling, and is usually quite dry in such places. The ore occurs in shoots, not yet well defined, because of limited development. Lastly, fine-grained zinc-lead ore occurs everywhere in the vein and in the adjacent foot-wall country deposits, but in several localities below the 5th level large deposits of copper ore occurred in and near the fault fissure, but no copper has been found to extend much above the 5th level.

Conclusions

1. Siderite replacement deposits in Leadville are of wide extent and of great significance in the future development of the district.

2. Siderite in Leadville primary deposits is of high manganese content, a true vein siderite, the prineipal source of manganese for the oxidized ores ('black iron') long a subject of geologic speculation and fruitful of discussions.

3. Siderite replacements are closely associated with intrusive gray porphyries, faults, and folded and sheared limestone. Siderite was one of the first minerals deposited in the fissures. It was also the last, and was present during the whole vein-forming period.

4. Siderite and sulphides are closely related, and doubtless of similar origin, being derived chiefly from intrusive porphyry emanations and deposited together in massive contact-metamorphic replacements. Siderite and sulphides have also been introduced through deep-seated fissures such as the Tucson fault, and may have been, in smaller part, derived from the Silurian sedimentaries through minor fissuring.

5. The Tucson fault preceded ore deposition in the Cambrian and Silurian formation and is older than the normal faults of Leadville.

6. The Tucson fault is coincident with the gray porphyry intrusion of Iron Hill.

Coal production of Colorado in 1913 was 9,232,510 short tons, worth $14,035,090, a decrease of 1,745,314 tons and $2,310,246 compared with 1912. This drop in output was due to the strike which has caused so much loss of life, discussion, and investigation.

Carbide Lamps and Explosives

Gas and dust was the cause of explosion which resulted in the death of Frank Hora at the Wheeling Creek mine of the Lorain Coal & Dock Co. on January 27, 1914. It was at first supposed that the residue from carbide lamps had caused the explosion; some of this residue was found in break-through 5, about 150 ft. from the centre of the explosion. As a preliminary, pending the investigation, a temporary order was issued forbidding the miners of Wheeling Creek mine to use carbide lamps. The local union passed a resolution demanding a thorough investigation, and refused to go to work unless allowed to continue using carbide lamps. In the meantime, chief mine inspector Davies, deputy inspector Gaffney, together with safety commissioner of mines, J. M. Roan, of the State of Ohio, aided by other deputies, officials and engineers were making a searching investigation. It was soon demonstrated that as the residue left by the carbide lamps is merely slaked lime it could therefore not be considered as a cause, and it was proved conclusively that even had there been fresh carbide in the break-through, it could not have had anything to do with the explosion, as the break-through was dry. Carbide will not give off sufficient gas, when exposed to the air, to cause an explosive mixture or an ignitable mixture unless brought in contact with actual water. The moisture in the air is not sufficient to make enough acetylene to ignite. There can never be an accumulation of gas produced from carbide by moist air, for the obvious reason that in order to produce gas, any air which has given up its moisture to produce acetylene must move on, and the acetylene goes with it. An investigation of the place where the carbide residue was found showed that as a matter of fact, this residue was shut off from the butt entry in which the explosion occurred by a substantial brattice, the residue being found within 3 ft. of the adjoining butt entry in break-through 5, and as before stated with a brattice between it and the butt entry in which the explosion occurred. The order prohibiting the use of acetylene was rescinded. J. W. Paul, of the U. S. Bureau of Mines, supplemented the investigation.

Fluorspar production of the United States in 1913 was 115,580 tons averaging $6.37 per ton, a small decrease compared with 1912. About 80% of the domestic output of fluorspar is consumed as a flux in basic open-hearth steel furnaces. It is used also as a flux in blast furnaces, iron foundries, and silver, copper, and lead smelters; in the manufacture of fluorides of iron and manganese for steel fluxing; in the manufacture of glass, enameled, and sanitary ware and of hydrofluoric acid; in the production of aluminum; and for many other purposes, according to the U. S. Geological Survey.

Manganese ore production of the United States in 1913 was 4048 tons. Imports were 345,090 tons.

FIG. 1. DISTILLATION FURNACE BUILDINGS, NATIONAL ZINC COMPANY.

The National Zinc Company, Bartlesville

By E. H. LESLIE

The smelter site of The National Zinc Co. is about 100 yd. to the east of the Bartlesville Zinc company's plant. Topographically the site of the National company is almost identical with the Bartlesville plant, being a level tract of land with a few slight depressions which are being used as dumping ground for retort residue. This Company is controlled and operated by Beer, Sondheimer & Co. and is the most modern of the Bartlesville group. The halftone, Fig. 1, and the sketch, Fig. 2, published through the courtesy of W. H. Gill, superintendent of the smelter, show in a general way the arrangement of the various buildings and character of the construction.

The zinc concentrates, which are being treated at this plant, are derived largely from the mills of Joplin, Colorado, Utah, and Butte. The concentrates are delivered at the plant in standard freight cars and unloaded by hand into storage bins at the ore house. There are 61 storage bins at the smelter with a capacity of 15,000 tons of concentrate. The concentrate is removed from the bins in buggies and taken to the dryers where it is dumped into the boot of an elevator and thus to the feed hoppers of the dryers. The dryer equipment consists of four 30-ton circular dryers of the same type as those used at the Bartlesville plant, the concentrate being fed at the centre of the furnace, is forced across the hearth by the four revolving rabble arms and discharged at the periphery. The power for the dryers is furnished by a 30-hp. Western Electric motor operating on a 220-volt, 115-ampere circuit. The dried concentrate is crushed by the usual Blake crusher and rolls, the material from the crusher going to a ¼-in. trommel screen and the oversize being re-crushed in a set of rolls. The dried product is elevated and conducted by bucket elevators to the feed bins of the roasting furnaces.

The roasting equipment consists of one 20-ton double hearth furnace, two 25-ton, and one 30-ton Zellweger furnaces. A brief description of the Zellweger furnace was presented in a previous issue.* The power for the furnaces is furnished by individual Hawthorne and Western Electric motors, a 40-hp. motor being used on the double hearth furnace and 30-hp. motors on the 30 and two 25-ton furnaces. The rabble mechanism is automatically controlled by a hydraulic starting and stopping device whereby one passage of the rabbles through the furnace is made about every six minutes. The feed to the furnaces is automatically dropped upon the hearth through a hopper at the bottom of the feed bins, the discharge being effected by a cam and tappet arrangement which is operated by a small motor. The 30-ton furnace is 156 ft. long while the hearth is about 16 ft. wide.

Roasted Sulphide

The roasted sulphide as discharged from the furnace contains from ½ to 1% sulphur in clean blende. This product is discharged from the furnace into hoppers and elevated by bucket elevators to brick storage bins. The roasted ore is drawn from these bins into tubs which are suspended from an over-head Sprague electric hoist and in this manner are carried to the mixing room.

The fuel used consists of coal from the Pittsburg, Kansas, field, Arkansas semi-anthracite, and coke. The fuel is delivered to the storage bins directly from the railroad cars. In the mixing room the various tubs of roasted ore, carbonate, and fuel pass over weighing scales and are dumped into the hopper of a concrete mixer. The furnace charge thus prepared in the mixer

*"Zinc Smelting at Bartlesville, Oklahoma," by E. H. Leslie, *Mining and Scientific Press*, July 11, 1914.

is dumped from the mixer into the furnace charge tubs which set in a pit in front of the mixer. The charge cars are then picked up by a 12-ton capacity Sprague electric overhead hoist and carried to furnace where it is charged directly by hand into the retorts of five blocks of furnaces. In the two other blocks of furnaces which go to make up the battery of furnaces at this plant, the mixed charge is elevated at the furnaces into suspended steel storage bins from which it is drawn into the hoppers of the Saeger charging machines.

The National Zinc Co. distillation furnace, shown in Fig. 3 and 4, is of the same general type as that employed throughout the natural-gas smelting region. The furnace is four rows high and comprises 19 sections of 16 retorts each. There is thus 304 retorts per furnace or 608 retorts to the block, making the total for the smelter 4256 retorts. The length of the furnace outside of the end walls is 102 ft. 10 in. while the height from the floor to the front skewback is 6 ft. 2 in. The pitch of the retorts is 4 in. The cylindrical retorts used are 50½ by 8½ in. inside measurement. Blow boxes or burners through which the air and gas enter the furnace are fitted to each half-section with the exception of the last four which have but one blow box to a section. The use of two blow boxes to a section has come to be looked upon as better practice than the single blow box which is used at the older plants. By thus increasing the number of fuel admissions a more uniform heat is obtained. The furnace blocks are supplied with air by individual fan blowers by which means the maximum pressure of about 2 in. of water is maintained. A sketch showing the general arrangement and construction of the furnace is shown in Fig. 3. The fuel consumption covering everything is about 1,000,000 cu. ft. of gas per block every 24 hours.

The Saeger Machine

One of the most interesting features in the operation of these furnaces is found in the employment of the Saeger machine, a front view of which is shown in Fig. 5, for the charging of retorts on two blocks of furnaces. While mechanical charging of retorts has found favor in Europe the introduction of the Saeger machine is an innovation in American practice. The pioneer work in that country which has been conducted with the Saeger machine at the National smelter gives promise of a wider field for its use in the operation of American zinc smelters. While the conditions for the most efficient use of this machine are not found in the American arrangement of furnace blocks, it is nevertheless in successful operation at this plant and is proving a valuable adjunct to smelter operation.

An idea as to the arrangement and construction of the charging machine is obtained from the accompanying side elevation sketch (Fig. 6) and the halftone, Fig. 5. It will be seen that the machine is mounted on a truck of 11-ft. gage and consists of a hopper bin with a capacity sufficient for charging one-half of one side of a block of furnaces. The bin is supported by a

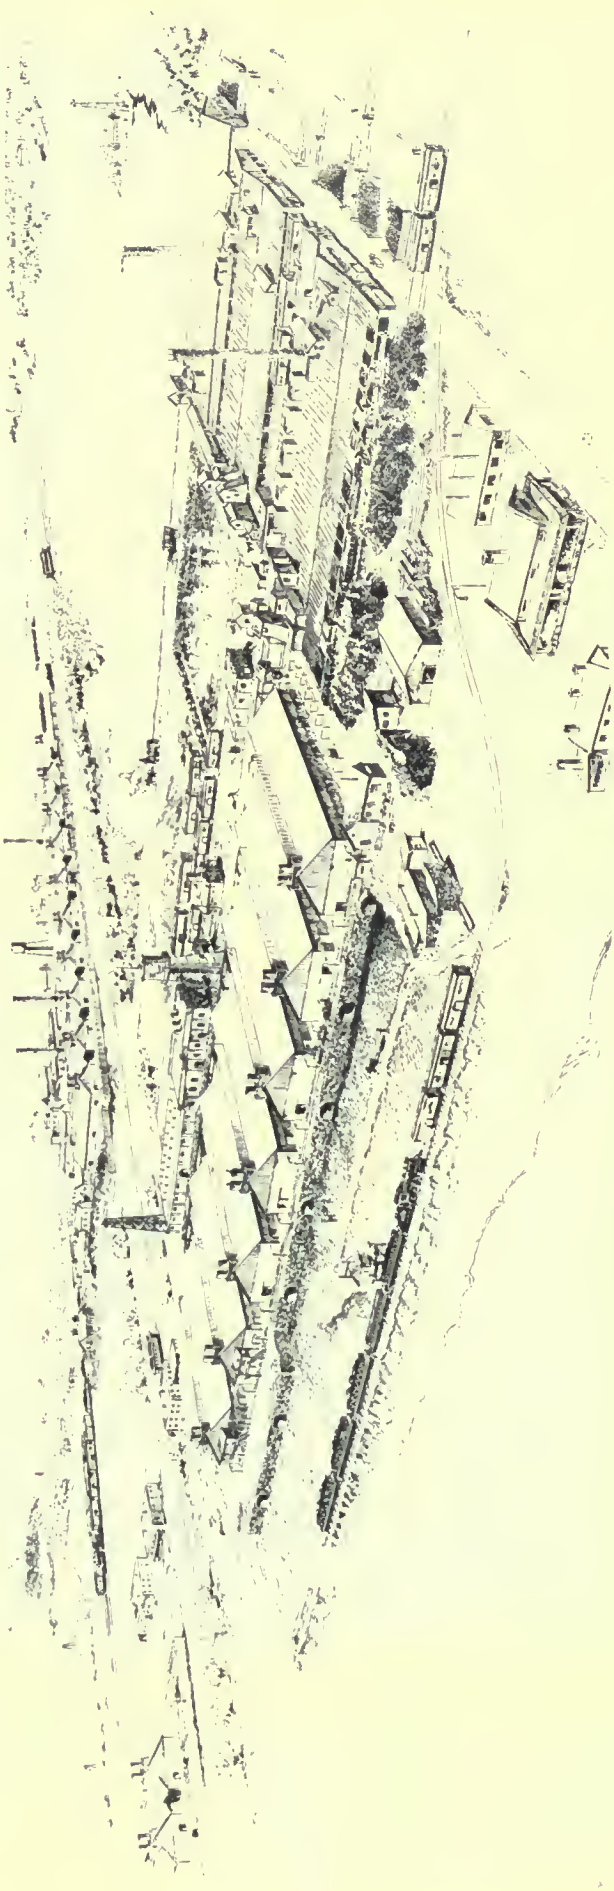

Fig. 2. National Zinc Company, Bartlesville Smelter in the Background.

structural steel column and bracing. The charge passes by gravity through a feeding device in the bottom of the bin and is conducted through individual pipe conduits to the eight spiral feeding devices which are so positioned as to enter and charge the eight retorts of one-half of a section of the furnace simultaneously. The machine. The operator is protected from the heat of the furnace by the iron shield seen in the illustration. In actual charging operations the charging spouts are inserted into the 8 retorts of one-half of a section of the furnace for a distance of about 44 in. or to within 5 or 6 in. of the back of the retort when the charge is forced

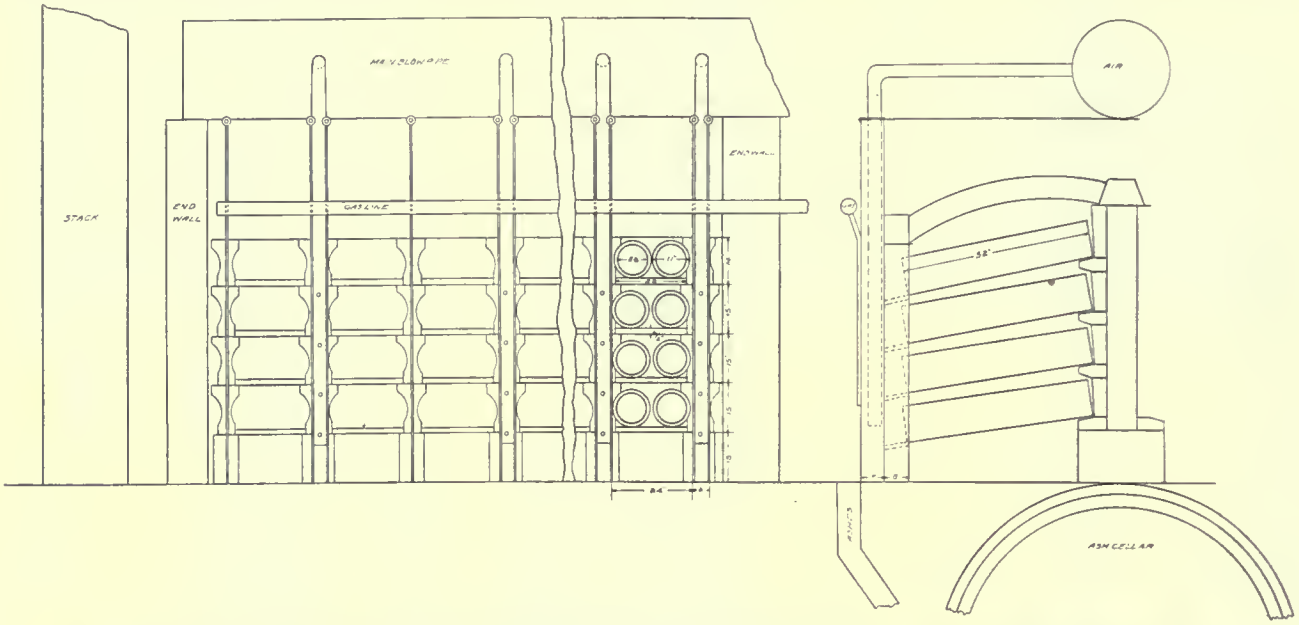

FIG. 3. SIDE ELEVATION AND CROSS-SECTION THROUGH DISTILLATION FURNACE AT NATIONAL ZINC PLANT.

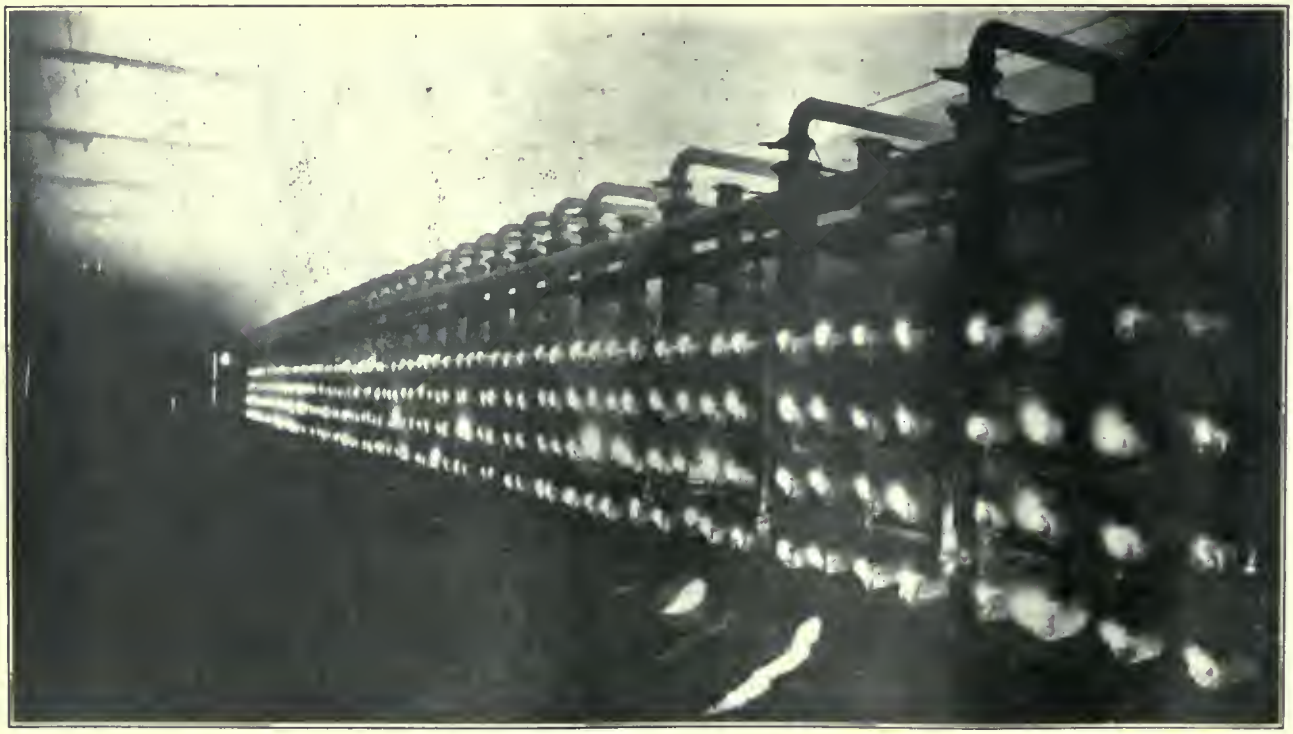

FIG. 4. NATIONAL DISTILLATION FURNACE IN OPERATION.

charging mechanism is mounted on a movable platform which moves at right angles to the trucks of the machine. This platform, with the chain drive for moving it is seen in Fig. 5. The movement is controlled by the operator who stands on an elevated platform, seen at the left of the half-tone, which platform is a part of the by the spiral feed through the spouts into the retorts. As the retorts become filled the spouts are gradually withdrawn from the retorts and when the spouts emerge from the retorts an automatic cut-off stops the feeding device. The compactness and uniformity of the charge is regulated by the operator keeping the load on the

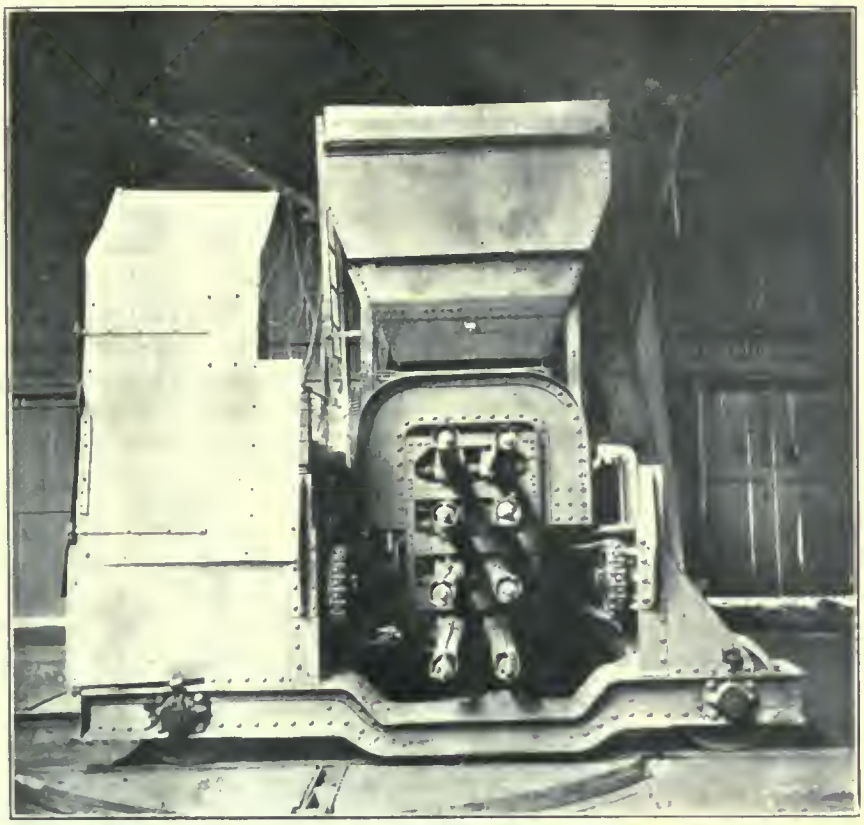

FIG. 5. FRONT VIEW OF SAEGER CHARGING MACHINE.

feed motor at a predetermined constant. When one-half of a section is charged the machine is moved forward and the operation repeated over the whole length of the furnace. Electricity for moving and operating the machine is obtained through a trolley. Since installing this machine several modifications have been made in it which include the placing of a small rod above the charge spouts for the purpose of leaving a hole at the top of the charge for the escape of the first gas that is formed in the retort. A small bucket elevator has also been added at the side of the machine by which any charge which is spilled on the floor during charging operations is returned to the bin of the machine. Blue powder is also handled by this elevator and subsequently charged. The last 4½ sections of each furnace are charged with blue powder. The machine is operated by two motors, one for locomotion and the other for operating the charging machinery. A small 2-hp. motor is used on the bucket elevators.

With the ordinary American arrangement of furnace blocks the charge storage bins which feed the machine must be placed at the end of the furnaces. It is therefore necessary to run the charging machine under the hopper of the feed bin, fill the feed hopper of the machine, move the machine to a turntable, which is situated at the end and at the side of the furnace, turn the machine around 90° to bring the feed spouts into the charging position, and then move the machine down the track and in front of the retorts. Since the hopper bin on the machine will only hold sufficient charge for one-half of one side of a block, it is necessary after this half has been charged to move the machine back to the turntable, transfer it to the tracks under the storage bin, re-fill the hopper bin on the machine, and again return to the front of the furnace. In European practice this difficulty, which occasions considerable loss of time, is not experienced. The blocks being arranged in series instead of parallel, the charged bins are situated at convenient distances along the front of the furnaces and when it is necessary to re-fill the hopper on the charging machine it is moved underneath one of these bins and little or no delay is occasioned. The turntable is not necessary in European practice and the cycle of operations is continuous. Even with the unfavorable arrangement of furnaces in American practice the machine has been found to possess many redeeming features, in that besides saving six men on the two blocks of furnace, in this instance it permits of the charging of from 1000 to 1500 lb. more concentrate to the side,

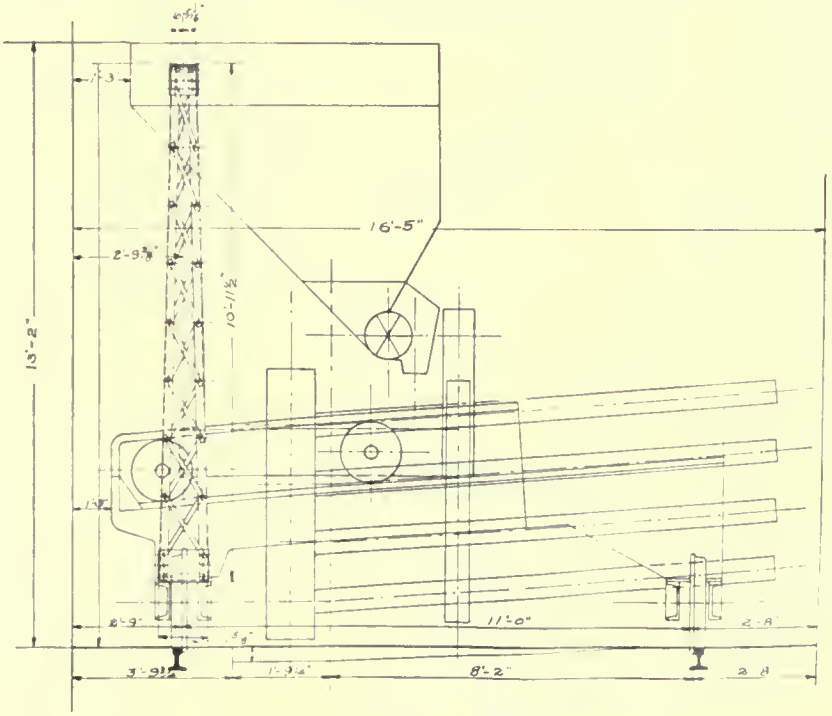

FIG. 6. SIDE ELEVATION, SHOWING OVER ALL DIMENSIONS OF SAEGER MACHINE.

and gives a more uniform charge and better results than hand charging, which is the general practice. By the use of this machine one side of a block of furnaces is charged in one hour.

The drawing of metal is conducted in the usual manner, a draw-car being used which moves over a track in front of the furnaces. The ladle is raised or lowered to position in front of the condensers by means of a hand winch, the operator being protected from the heat of the furnace by a metal shield. The zinc is drawn three times a day; at 3 p. m., 11 p. m., and 4 a. m., cast into slabs and removed to the stock pile, Fig. 7, for shipment. The average charge of roasted ore is about 15,000 lb. to the side of a block or 15 tons to the block, thus giving the plant a capacity of approximately 105 tons per day.

Water is used for discharging the retorts. A hose with nozzle is connected with the water pipe-line directly in front of the furnace with convenient taps to which the hose may be attached. In cleaning the retorts the operator is protected by means of a sheet iron shield which is suspended from a rail along which it can be moved in front of the furnace. Any slag which is not removed by the steam, which is immediately formed when the water enters the retorts, and which sticks to the sides of the retorts, is removed by means of scrapers.

Discharging Machine

In connection with the discharging of retorts, it may be stated in passing that the discharging machine which was imported simultaneously with the Saeger charging machine, was found, after a thorough trial, to be unsuited to American practice and has been discarded. The chief difficulty in the use of the discharging machine was found to be that it shook up the retorts unnecessarily and thus brought about mechanical difficulties in the operation of the furnace. With muffle retorts this machine no doubt would be a success.

The retort furnaces are of the cellar type and the residue as discharged from the retorts falls into a chute at the front of the furnace and is conducted to cars underneath. The cars are subsequently removed to the dumping ground at the rear of the furnace blocks. Some of the residue is used for railroad ballast, some dumped, and that derived from the ore, which carries silver, is either clinkered at the plant of the Bartlesville company† or shipped to the blast-furnace plants. The average life of the retorts is about 30 days, while the condensers last about 10 days.

The pottery is equipped with all the necessary machinery for supplying the plant with retorts and condensers. St. Louis clay, received at the plant in the ordinary freight cars, is dumped at the pottery building where it is given a preliminary weathering. The crushing equipment consists of a 14-in. Blake crusher, the discharge from which is elevated by a bucket elevator and discharged into the hopper of the primary rolls. The discharge from the rolls is conducted to a four-mesh screen, the undersize from which goes direct to the pottery bins, while the oversize is re-crushed in a second set of rolls and is thence returned to the screen.

Making the Retorts

The clay is pugged in a small mill from which it is removed, cut into convenient size for handling, and allowed to season for three or four days. This material is then taken to a second pug-mill and re-pugged, the product thus obtained being ready for the manufacture of retorts. The material used consists of a mixture of 1000 lb. of clay to 1250 lb. of adobe or burnt clay. In the manufacture of retorts the Mehler hydraulic press is used. This press has a capacity of 250 retorts per shift of nine hours. The retort department of the pottery is handled by five men. As the retorts emerge from the press they are taken on carriages to the dry rooms of which there are twelve. These dryers are heated by steam coils placed in both the floor and ceiling of the rooms. By this means a temperature of about 110°F. is maintained. The twelve drying rooms have a capacity of 1100 retorts each. The retorts are kept in the dryers for about 60 days before being used in the furnaces. From the dryers they are taken on cars by a 30-hp. Jeffrey locomotive to the annealing ovens which are situated at the furnace blocks and are here tempered for about 12 hr. before being put into the furnaces.

Fig. 7. Spelter stock piles.

The condensers are made of a composition of one-half clay and one-half crushed old retorts. The material is mixed and pugged in a small pug-mill and subsequently molded in a Vannatti condenser machine. This machine is operated by two men and has a capacity of from 1000 to 1200 condensers per shift. The condensers as taken from the machine are allowed to stand for a day and are then crimped; this operation consisting of shaping the base of the condensers to conform with the retorts. They are then dried for about a week and burnt for use at the furnaces. The burning requires about 26 hr. The kiln used for this purpose has a capacity of 2500 condensers.

The boiler room equipment consists of three 72 by 18-

†"Zinc Smelting at Bartlesville, Oklahoma," by E. H. Leslie. *Mining and Scientific Press*, July 11, 1914.

ft. horizontal return-tube boilers, built by the Frost Manufacturing Co., for a steam pressure of 125 lb. per square inch, which supply steam to the engines operating the electric generators, and one 72 by 18-ft. boiler of the same type built for 100-lb. pressure per square inch, which is used for dry-room service. The boiler feed water is supplied at a temperature of 190°F. by a Blake 7½ by 5 by 6-in. pump.

The generator equipment consists of three units arranged as follows: One 18 by 36-in. St. Louis Corliss engine direct connected to a 200-kw., 250-volt, compound-wound direct-current Western Electric generator operating at 120 r.p.m.; one 16 by 19-in. Chuse 4-valve engine, direct connected to a 125-kw., 250 volt, compound-wound, direct-current Sprague generator operating at 190 r.p.m.; one 15 by 14-in. Skinner engine, direct connected to an 80-kw., 250-volt, compound-wound, direct-current Western Electric generator, operating at 300 r.p.m. The switchboard consists of four 24 by 84-in. panels of blue Vermont marble, equipped with circuit breakers and Weston and Keystone instruments.

This plant is the most modern of the Bartlesville group of zinc smelters and the work being done is most commendable, from both a mechanical and metallurgical standpoint. While details as to charges, costs, and exact metallurgical results are not available for publication, the plant is extracting about 85% of the zinc content of the concentrates treated and as long as gas is available in the district and there is a market for spelter, will be operated profitably.

An Impression of the Rand

We give herewith a portion of letter recently received from an Anglo-American mining engineer known to many of our readers and recently on a short visit to Johannesburg:

"The Rand is certainly a great goldfield, and shows no sign of failing as a large factor in the world's supply of gold. There is a tendency, of course, for the original outcrop mines to play out, signs of this fact are demonstrating themselves fairly rapidly; on the other hand, the deep-level mines of the East Rand are showing up very well. Recently the State has had a hand in gold production of its own, and the experiment is being watched with interest.

"There is very little doubt that there are large areas in the East Rand district that remain untouched, but attention has turned that way, and it seems probable that one by one there will be new mines developed, and in the course of a few years the production will move from the Johannesburg district to the East Rand. The Modder 'B', Modder Deep, Brakpan, and Van Ryn Deep all have a life of from 20 to 50 years.

"The predominating factor in the success of the mines is the labor condition, to which is closely allied the political; in fact, it is difficult to talk about one without bringing in the other. The Boers are the real owners of the country as much today as before the war. They are, however, divided into two factions, the old pig-headed type headed by Hertzog, whose only desire is to drive everyone out of the country that wants to do anything except sit on the *stoep* and smoke, the more sane and ambitious faction being led by Botha, who is kept 'on the fence' with the *backveldter* on one side and the mining interests on the other. Then there is the English party, or mining interests, with Merriman as an offshoot with a small coterie which looks after the interests of the colored people other than the kraal 'nigger'. Last, but not least, is the Labor party, which is being led at the present time by disgruntled failures in mine management, such as Cresswell, Poutsma, and others. This is a strange mixture to form into a sane and constant government to work for the best interests of the premier industry of the country.

"Mining has always been the 'bone of contention' in Africa, and it looks as though it will remain so in spite of the fact that a bloody war has been fought over it. It seems to have done little good toward the permanent peace of the country, the only difference being that the flag of another country flies over Government House, and a few Dutchmen have got titles.

"The supply of Kaffir labor is short at the present time by 40,000 boys, in spite of the fact that the last three years have been very dry; indeed, the one word that is on everyone's lips is 'drought'. This condition should have forced the native from the kraals to the mines, and undoubtedly it has, but still the supply of labor is scarce. It is easy to foresee what will happen when the cycle changes and there are several wet seasons favorable to the native's natural agricultural instinct. This same drought condition has also forced many young Dutchmen to the mines, as there is no work on the land.

"White labor is making itself impossible, and forcing itself out of the mines by its own foolhardiness. It is being replaced, selected natives of intelligence being given jobs other than common labor which were formerly held by white men. This is the natural outcome of the tyrranical behavior of the labor leaders.

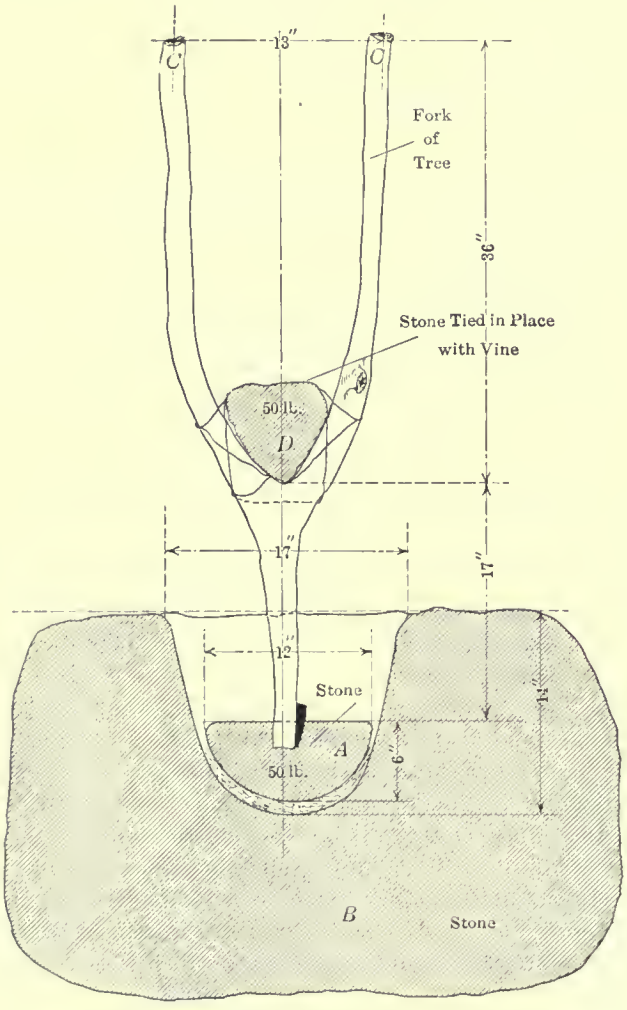
"Merriman is raising the 'color bar' question, and there is little doubt that before long, with or without favorable legislation, the 'tar-brush yellow' or half-breed mechanic of the Cape and Natal will find employment in the mines, replacing the pure white at lower wages and less trouble to the mine-owner, at any rate for the time being.

"While it is necessary for this condition to come about, one has to pause and look ahead a few years for the result of such a policy, and the only conclusion that can be arrived at is that the educated colored man will be supreme in Africa."

A Crude Method of Disposing of Cyanide Slag

By ARTHUR FEUST

In some recent work in Central America I had to solve the problem of disposing of a small quantity of cyanide slag, and the Latin-American *molinette,* shown in the accompanying sketch, was suggested to me by my native foreman. It was finally adopted as the cheapest and most efficient method under the circumstances, freight to San Francisco, California, costing $76 per ton. These molinettes are used by the 'high-graders' to recover the gold from stolen ore. The base or bowl of the



THE MOLINETTE.

molinette, as shown in the illustration, is made in a hard, close-grained rock which is hollowed out by fire and cooling with water to crack the rock, this being repeated until a sufficient depth has been attained. The rough or projecting parts are then trimmed up with a chisel. A fairly round stone, *A,* is selected for the head, and a hole drilled in its upper side to receive the fork, *C C,* which is wedged into place. To the fork an extra weight, *D,* is fastened by the aid of vines. In order to smooth the bowl, *B,* fine gravel is used with a little water and the molinette is operated for a day or two in this way until it has become polished on the inside.

The molinette is operated as follows: first the slag is broken down to pass a No. 10 screen and, for the size molinette illustrated, five pounds of slag forms a charge. Just enough water to make a thick paste is added, since if excess water is used the operation is delayed, as with a thin pulp in a tube-mill. Quicksilver is added according to the richness of the slag. The operator then puts the head *A* into the bowl on top of the slag, water, and quick, and grasping the ends of the fork *C C* begins to revolve the head, *A,* at the same time giving a rolling or twisting motion so as to smear or brighten small shots of metal. After the slag becomes slimed a trifle, some more water is added, then the slime is washed away and the coarse particles reground until the entire quantity of slag is slimed. When the amount of slimed slag in the bowl becomes small the entire mass is scooped up with a piece of dry gourd into a Russia iron pan and covered with cold water to congeal the warm amalgam. The rest of the slime is then washed off and the remaining amalgam squeezed dry. It is now ready for retorting.

I have had one of these molinettes made for a sum in Nicaragua equivalent to $8. One hundred pounds of slag can be cleaned up in a day, using two men, one to treat the slag and one to work the molinette. The slag in question weighed 600 lb. and the bullion recovered was worth $379.89. The slag discharged was assayed and found to be worth $25.03 gold and $2.78 silver per ton, or a total of $28.41. Bullion thus recovered is free from the metallic iron which is present after regrinding in an amalgamating barrel.

THERE ARE 15 coke-making establishments in Colorado, which operate 3588 ovens, all of the beehive type. Six of the establishments, operating 726 ovens, were idle throughout the year. In addition to these idle plants, 980 ovens were idle at plants that made some coke in 1913, so that the total number of idle ovens was 1706, representing nearly half the coking capacity of the state. No new ovens were under construction at the end of the year. The output of coke in 1913 was 879,461 tons, valued at $2,815,134, according to E. W. Parker, of the U. S. Geological Survey. The decrease as compared with 1912, amounting to 93,480 tons in quantity and $228,860 in value, was due entirely to the labor troubles among the miners, and not to adverse trade conditions. The principal disturbances were in Las Animas county, the leading coal-producing and coke-making county, and resulted in a decrease in coal production of nearly 1,000,000 tons and in the whole of the decrease in the output of coke.

DUTY of the Oroya Links 50-stamp mill at Kalgoorlie in 1913 was 7.9 tons per stamp-day. Ore treatment cost $2.05 per ton, the extraction being 92.25%, and residue average 44c. per ton.

The Eruption of Mount Lassen

By WILLIAM H. STORMS

The recent renewal of volcanic activity at Mt. Lassen, in Shasta county, California, has attracted much attention from scientists, engineers, geologists, summer tourists, and others, many of the more venturesome climbing the steep slope of the ancient volcano and gazing down into the ugly pit near its summit, that now constitutes the so-called crater. Some have contended that it is not a volcano at all—merely a geyser. Having personally visited the mountain, inspected the crater, and examined the material thrown from it, and escaped without damage, I am compelled to say that the recent explosive antics of Mt. Lassen in no sense resemble a geyser. While it is true no fresh lava has, as yet, been ejected by this, the newest volcanic vent in the United States, the demonstration, in my opinion, is distinctly that of a volcano—in embyro, perhaps, but a volcano, nevertheless.

What has recently actually taken place at Mt. Lassen is easily described. In the latter part of May last a moderately heavy shock was felt by the inhabitants of that sparsely settled region. On May 30 the report was published that a forest ranger on duty in the Lassen region had observed a fissure near the summit of Mt. Lassen from which a large volume of steam was being emitted. A day or two later there were reports that a crater had formed from which ashes and lava were being ejected. Several eruptions occurred, some of them of spectacular proportions, and notwithstanding the frequently repeated statements published that it was only a geyser, it became evident to those who could see the mountain, even from a distance of 100 miles, that something very unusual was in progress. On Sunday morning, June 14, the volcano had quieted down so that little, if any, steam was visible from a distance, and a number of faithful watchers who had been patiently waiting for an eruption, had about given it up as a hopeless vigil, when, without any warning whatever, at 9:45 o'clock, a huge black cloud burst from the summit of the mountain, ascending to great height and then spreading out like an immense mushroom. In a few minutes the dust-cloud and the heavier gases began to descend, and these soon enveloped the entire mountain and the surrounding region within a radius of 4 to 5 miles, and dust settled to the southward and southwestward to distances as great as 7 to 10 miles. On the evening of the same day, at 6:30 o'clock, a second but smaller eruption occurred.

The following day I went to Mineral, in Battle Creek meadows, and for several days thereafter explored the region on the south and southwest sides of Mt. Lassen. Finally, on June 20, I with three other men, with saddle-horses and pack animal, rode to within 3000 ft. of the foot of the trail leading up the steep slope of Lassen on the south side. A small cloud of steam was observed at intervals issuing from a fissure amid the rocks, far up the mountain side, and as we learned subsequently, 2000 ft. southeasterly from the main vent. When the sun had melted the snow sufficiently to make walking safe, we started for the crater, 2000 ft. above us and nearly 1½ miles distant. Arriving at the summit, the crater was seen on the opposite slope of an amphitheatre-shaped basin, and about 700 ft. distant. It had greatly increased in size over the dimensions given in the early reports. I found it to be about 650 ft. long, 100 to 150 ft. wide, and 100 ft. or more in depth. While its width is being constantly increased by the caving of the walls of the crater, the depth is being diminished from the same cause. It looks like a big open-cut, or glory-hole, and a miner watching the ground surrounding the vent would say the ground was working. Cracks could be seen on the surface about the crater, extending back from the rim from 100 to 200 ft., and it would seem that this moving mass must eventually all fall into the crater.

THE CRATER OF MOUNT LASSEN.

It was evident that a new fissure had formed extend-

ing from near the summit of the mountain in a southeasterly direction for nearly half a mile—how much farther I do not know, as there was at that time no visible evidence of it on the surface beyond the limits mentioned. This fissure undoubtedly extends to great depth, and is a conduit for steam generated far down below the surface. It may be that a mass of molten rock exists below, which, coming in contact with water, generates the steam which follows the line of least resistance, the open fissure, to the surface. When clogged at the surface, the steam and sulphurous gases accompanying it, being unable to freely escape, accumulate until there is sufficient energy developed to blow out the obstruction. This resulted in the formation of a small pit, described by the forest ranger as being 40 by 25 ft., and only a few feet deep. The crumbling walls of this cavity caving into the pit, once more sealed the vent, when a second blow-out took place, enlarging the hole. Again and again this process was repeated until the two eruptions of Sunday, June 14. By June 21, the day on which I saw the crater, it had been enlarged by these repeated explosions to a hole 650 ft. long and over 100 ft. wide.

When at the summit, Mt. Lassen is seen to be a cluster of four peaks. At the highest point of the southeast peak of the four forming the main summit mass, is situated the observatory of the Forest Service. This building was used as a watch-tower by the forest rangers. The observatory is well ventilated by the holes made by the falling rocks thrown out of the crater. The disposition of the several peaks and their connecting ridges forms an amphitheatre-shaped basin, the sloping floor of which is from 100 to 200 ft. below the surrounding ridges and peaks. The new crater lies along the northerly side of this depression, extending from near the summit of the northwesterly peak in a southeasterly direction to the saddle connecting the northeast and southeast peaks. The new vent cannot be seen from any point outside of this crater-shaped basin, as there is no other mountain near that is sufficiently high to permit one to look into the basin.

It has been reported that flames and molten lava have been seen at the crater. This is untrue, or was up to June 21. There were icicles hanging in festoons along the north rim of the pit on June 21, and the only evidence of heat was where the steam was slowly rising from each end of the rift, the central portion having been filled in by the caving of the walls. Sulphur was being deposited on the rocks adjacent to the steam vent, and sulphurous gases could be detected all over the mountain-side, though this was no doubt in part due to the smell of the damp sand that had been thrown out from the vent.

Lassen peak is of volcanic origin, and so are all of the mountains and hills within many miles of it, many of them being, like Lassen itself, extinct craters. To the westward about 5 miles is a rugged peak known as Brokeoff mountain, that has every appearance of being a portion of the rim of an ancient volcano that must have been very much higher than Mt. Lassen now is. What was probably the central part of this old crater is indicated by the two solfatara called Soupan Springs and Bumpasses Hell. From this vicinity the rocks dip away on all sides as from a central vent. The Cinder Cone is 11 miles a little north of east from Mt. Lassen. It has the distinction of having been the last eruption of volcanic rock to have occurred in the United States. Just when that eruption occurred is not positively known, but is placed at from 100 to 200 years ago. Whether the present disturbance at the summit of the dominant peak of the region will result in a flow of molten lava, I am unable to predict, though such an eruption would be in no way surprising.

The Lassen Peak region is one full of natural beauty. There are grand forests of pine, fir, tamarack, and other trees; bright streams teeming with fish; there are hot and mineral springs; geysers, lakes of boiling mud; sulphur deposits; great faults; fields of basalt, andesite, and tuffs. In short, it is a paradise for the geologist, the hunter, the fisherman, or the scientist in search of a volcano, either old or new. I have but one word of advice to offer: If the mountain is steaming, it is fairly safe to climb up and look at it; if it has ceased to steam, it may be extremely dangerous to approach the crater, for it may explode without a moment's warning, and the region of the crater would then be a most uncomfortable place, for, if not hit by flying rocks, the poisonous vapors and gases would quickly asphyxiate anyone who may be enveloped by them.

Gold Production of Siberia

The eight Russian gold-smelting laboratories produced in 1913, 106,901 lb. troy of 'schlich' gold (crushed gold ore), which yielded 104,155 lb. of pure gold equal to 1,249,860 oz. In 1912, the production of these laboratories amounted to 100,290 lb. of schlich gold, yielding 97,828 lb. pure gold. In 1912 the strike at the Lena goldfields had considerable influence on the output of the district. The increase in 1913 was due entirely to the activity of the Bodaibo laboratory, which produced about 7200 lb. more than in 1912.—*Daily Consular Report.*

GOLD OUTPUT of the Consolidated Mines of New Zealand, at Reefton in the South Island, were as follows in April:

Mine.	Tons.	Yield.	Cost per ton.
Blackwater	4,283	$38,000	$4.80
Progress	3,470	21,000	4.48
Wealth of Nations	2,080	14,000	4.56

A CORRECTION.—In the article upon 'Flotation Tests at Mt. Morgan' by William Motherwell, printed June 27, it should have been stated (page 1046) that all samples had been dried before being tested by the *cyanide* process; also that the grading tests showed the finest grade of ore as well as finest grade of concentrate was richest.

DISCUSSION

Readers of the MINING AND SCIENTIFIC PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Solution Control in Cyanidation

The Editor:

Sir—I have not hitherto joined in this discussion because, being situated so far away as Central America, I thought my contribution would be stale before it could reach your readers, but since I notice in your issue of March 7 that my name has been brought in I think I ought to offer some comments.

It seems to me, first, that the controversy between Messrs. Allen and Colbath has been needlessly confused owing to that common mistake, a failure to define terms. They both use the expression 'direct titration', and yet each is thinking of a different reaction which gives entirely different results, and both writers are probably right from their own points of view.

I may say that I am in agreement with Mr. Allen in his contention that the silver nitrate titration to yellow opalescence with KI indicator is useless as a measure of the 'free' cyanide content of a working solution containing zinc, because, as he rightly observes, if the protective alkalinity is fairly high, (in my experience from 0.06 to 0.08% in terms of NaOH) the reading so obtained will coincide exactly with that of the so-called total cyanide shown by titration to the same yellow end point after addition of excess of caustic alkali.

On the other hand, I agree with Mr. Colbath in thinking that in defense of a large number of cyanide workers, among whom I number myself, a protest is due against Mr. Allen's unkind assumption that the method he criticises is in universal use, and that up to the time he published his article we have all been accustomed to consider our total cyanide as being the free cyanide content of our working solutions, or at least that we have been hopelessly at sea with regard to what that free cyanide content really was. I admit that the method in question is widely used, and I think with him that it may be responsible for many of the curious experiences we read of from time to time, but it is certainly not universal. My own practice during the 20 years in which I have been connected with the process has invariably been, except in the absence of zinc, or in the presence of much copper, to titrate for free cyanide without KI indicator, using the first faintly visible white opalescence as the end point, and this is the practice of many independent workers of my acquaintance.

Mr. Allen asks, rather incredulously, what is the compound of zinc and silver nitrate responsible for the opalescence. I have no personal data to offer on this point, but it is usually considered to be due to a precipitation of the zinc originally held in the solution as double zinc cyanide. It would presumably be cyanide of zinc, unless ferrocyanide be present in which case it would be zinc ferrocyanide. It is not considered to be silver owing to the fact that it appears long before the formation of the yellow iodide of silver. It becomes visible at a definite stage of the titration, and though Mr. Allen and Mr. Clennell, among others, have not been able to make use of it, it yields results of considerable precision in the vast majority of the cases that have come under my observation. I admit, however, that it needs care and practice to distinguish this end point as it is not nearly so easily seen as the yellow silver iodide reaction. Moreover, for a person passing from one mine or mill to another it is often necessary to practice afresh with, say, a dozen titrations, before precision is attained, owing to differences both in the light and in the composition of the solution. In spite of all this, an ordinary solution man unaccustomed to the method will in a couple of days be able to check his own readings within 0.004% KCN.

Mr. Allen may object that, even granting that there is a definite end point, which he personally has not been able to discover, no one can say that this point indicates free cyanide, or indeed has any significance whatever. Well, I suppose that to each man his own practical experience goes for something, and I have found that the figure so obtained harmonizes very well with my actual results. In support of the theory I may quote Bettel* who states that if the exact end point can be caught the figure so obtained represents the free cyanide plus 7.9% of the potassic zinc cyanide present. His only doubt seems to be whether that end point can be detected, especially in the absence of ferrocyanide. For practical purposes I myself have no doubts on that score. This question has also been carefully discussed by Gerard Williams in a paper published in the *Journal* of the Chem. Metal. and Min. Soc. of S. A. for, I think, March or April 1904, and a similar conclusion arrived at.

Since reading Mr. Allen's article I have made some titrations bearing thereon which will serve to illustrate the points I have raised. I will deal first with the rather positive generalization, "in the presence of zinc compounds there is no definite end point to be observed." I took a sample from the barren solution sump at the mill where I now am and placed it in a well stoppered bottle. I made three titrations on this solution myself and had the cyanide superintendent also to make three.

*Clennell, 'Chemistry of Cyanide Solutions,' page 24.

in every case avoiding looking at the burette, and having a third person to record the readings, neither of us seeing the results until all the tests were finished. 25 c.c. of solution was taken for each, no KI was added, and the end reaction noted was the first faint cloudiness that became visible, resembling a pale blue smoke haze.

The first series was made late in the afternoon when the light was bad and therefore the results are not as uniform as those in the second which was made next morning on the same sample. My figures are marked 'A' and those of the cyanide superintendent 'B'.

First Series

A		B	
1	0.068% KCN	1	0.064% KCN
2	0.072% KCN	2	0.068% KCN
3	0.066% KCN	3	0.068% KCN

Protective alkali 0.06%
(in terms of NaOH)
Total cyanide ..... 0.198% KCN.

Second Series

A		B	
1	0.068% KCN	1	0.066% KCN
2	0.066% KCN	2	0.066% KCN
3	0.066% KCN	3	0.066% KCN

These results surely indicate that the method is capable of great precision, and this is not a solitary instance, equally precise results being obtained at the great majority of the mills I have been called on to visit from time to time.

Perhaps I should explain that in addition to the precautions of absolutely transparent solution and clean flask, the incidence of the light is of supreme importance. I find that the best plan is to have the burette opposite a window and place a black card vertically a few inches behind the flask, holding the latter so that the light will strike it just over the top edge of the card but will leave the solution itself in shadow. The flask used should preferably be not very wide at the bottom, so as to give a good depth of solution. Then, keeping the eye on a level with the flask, watch the behavior of every addition of silver nitrate as it touches the solution, not keeping it in continuous agitation but allowing the blueish white cloud formed by each addition of silver to hang for a second or two before agitating and dissolving. The finish is indicated, as already described, by the first appearance of a blueish tinge dulling the original brilliancy of the solution.

Coming now to the method advocated by Mr. Allen, it is not clear to me whether he titrates to the white or the yellow end reaction. He speaks of a 'distinct opalescence', but that word is, unfortunately, used indiscriminately by writers on this subject to indicate a turbidity without any specification as to color. On first reading his article I took for granted that he was speaking of the yellow silver iodide opalescence, but on turning up the reference in Clennell, I find that the latter expressly states that the end point he recommends is a white flocculent precipitate. I should like to say in passing that unless a titration is to be carried to the yellow end reaction I cannot see the object of adding KI at all, as I have never been able to find that its presence or absence makes the smallest difference when reading either to the first faint white opalescence or to the white flocculent precipitate end point.

I began my experiments by using the yellow end reaction but my first six attempts were so hopelessly erratic that I began to look for the variable factor. The only possible one I could see was the quantity of KI, which I had added in each case from a dropping bottle without regard to amount. I then made a systematic series counting the drops of KI (5% solution) from a burette and increasing the number each time, taking 25 c.c. of cyanide solution for my test.

Third Series

1	using	5	drops of	5%	KI solution	0.100%	KCN
2	"	10	"	"	"	0.092%	"
3	"	15	"	"	"	0.086%	"
4	"	20	"	"	"	0.082%	"
5	"	25	"	"	"	0.080%	"
6	"	30	"	"	"	0.078%	"
7	"	35	"	"	"	0.078%	"
8	"	40	"	"	"	0.076%	"
9	"	45	"	"	"	0.076%	"
10	"	50	"	"	"	0.076%	"

Each time I obtained the unmistakable yellow opalescence, but the readings varied considerably. There seems, however, to be a halting place in the series at 40 drops where uniform readings may be secured.

I next turned my attention to the white flocculent precipitate end point recommended by Clennell. I found that the transition from a white opalescence to a white flocculent precipitate was very difficult to distinguish and seemed to be almost as much influenced by the time expended in the operation as by the amount of $AgNO_3$ used. After practising for a while, however, I obtained some fairly concordant results which are here given:

Fourth Series

1	No KI	0.086%	KCN
2	No KI	0.076%	"
3	10 drops of KI	0.070%	"
4	20 " " "	0.076%	"
5	40 " " "	0.076%	"

The KI does not appear to affect the result in any way, thus confirming my previous experience, but the general tendency is to check No. 8, 9, and 10 of the third series.

It would appear from all these figures that the method is difficult and lacking in precision when the aim is to end at the white flocculent precipitate, but that when carried to the yellow opalescence concordant readings may be obtained provided that sufficient KI be used, the amount suggested by the third series being at least 40 burette drops, or about 2 c.c. of 5% solution for 25 c.c. of cyanide solution to be tested.

The question may be asked, "Why go to so much trouble about a free cyanide determination, which is admittedly only relatively correct, when the total cyanide titration gives more uniform readings, is more easily performed, and should be just as effective when once its

dissolving value has been established for a given set of conditions?'' This contention would be all right if it be admitted that the zinc potassium cyanide is equal to free cyanide in dissolving power, but if not, as I think most will agree, then the objection lies in the fact that the ratio of free to total cyanide is not by any means constant in a working solution but varies from day to day with changes in alkalinity and zinc content, so that a total cyanide determination may tell very little about the active property of a solution.

Regarding the regeneration of cyanide by addition of alkali, Mr. Allen seems to be trying to picture a permanent restoration of free cyanide which will persist independently of changes in alkalinity. I believe that those who favor the idea hardly understand it in this sense, but rather as a temporary dissociation between the cyanide and the zinc compound, which persists only so long as conditions remain constant, and if so, 'dissociation' would be a better word than 'regeneration'. If, however, while in this condition it acts on the metals in the same manner as free cyanide it ought surely to be registered as such, for purposes of solution control.

Discussions on the subject seem invariably to be based on the assumption that the alkali added is a caustic, but since lime is almost always used in commercial practice it would seem necessary to study the matter in the light of this reagent. I think it probable that if the conventional equations were considered from the standpoint of the substitution of lime for caustic the conclusion would be somewhat different, and that some part at least of the cyanide indicated in my method of titrating as having been freed from combination might be shown to be permanently regenerated in the true sense.

For instance, on adding a clear solution of calcium hydroxide to one of zinc potassium cyanide a white precipitate is thrown down, which I believe to be insoluble calcium zincate. It forms rather slowly and may take from 5 minutes to half an hour, but once formed it seems to be quite unaffected by additions of free cyanide, indicating that the reaction is not reversible. In this case there would be a very different condition of affairs to that usually assumed, because here the zinc of the double cyanide would be removed out of the sphere of further action and would not be liable to reversal on variation of the conditions.

To what extent this may take place in ordinary practice I cannot say, but I have for a long time accepted it as a probable explanation of the 'mysterious' disappearance of zinc out of working solutions.

Following up this point a little further I took a fresh sample from the barren solution sump and titrated in the various ways. For the determination of free cyanide by the method recommended by Mr. Allen, which I have called 'Clennell's method', I added 50 drops of 5% KI solution and carried addition of $AgNO_3$ to the yellow opalescence. In the following table I mean by 'direct titration' the method I use, as previously explained. 'Clennell's protective alkalinity method' refers to the direct titration for alkali after determining free cyanide, as described in 'Chemistry of Cyanide Solutions,' page 63. This works well under the conditions of previous silver nitrate titration as I have described them, because by stopping addition of nitrate at the earliest possible point the interference of the acid zinc nitrate is avoided.

Fifth Series

Free KCN direct titration.	Free KCN Clennell.	KCN total.	Protective alkalinity Clennell.	Protective alkalinity Green.
0.082%	0.094%	0.214%	0.066%	0.066%

A portion of this same solution was then agitated in a stoppered bottle with excess of dry slaked lime for one hour, and then filtered and titrated.

Sixth Series

Free KCN direct titration.	Free KCN Clennell.	KCN total.	Protective alkalinity Clennell.	Protective alkalinity Green.
0.164%	0.086%	0.214%	0.194%	0.214%

Now there are several points to be noted in comparing these two series.

1. The free cyanide shown by 'direct titration' is doubled after addition of lime.

2. The free cyanide shown by 'Clennell's method' is less after adding lime than before. This surely would suggest something wrong with the process, because though the figure might not necessarily be greater after adding lime there seems no obvious reason why it should be less.

3. The two methods of computing protective alkalinity, which checked exactly in the case of the original solution, do not check after the alkalinity has been raised.

In No. 3 we have the key to what seems to me the weak spot in the Clennell method for free cyanide advocated by Mr. Allen. Assuming that it is capable theoretically of indicating the true amount, which Clennell himself is inclined to doubt, its correctness is vitally dependent on a true value being found for protective alkali. Does Green's method afford a sufficiently correct value for the purpose? Here again Clennell doubts whether the figure so obtained represents the protective alkali according to the usual definition. In the series shown above there are two different values for alkalinity resulting from two recognized methods of determination. Assuming that neither is absolutely correct, which of the two gives the closer result? No doubt for purposes of solution control the two readings in the sixth series form a sufficiently close check, but when used as a measure for neutralization preparatory to the free cyanide titration the difference is anything but a negligible quantity. For instance, I repeated this determination for free cyanide using the basis of the lower alkali reading and obtained a value for free cyanide of 0.134%. Compare this with the figure 0.086% resulting from the use of the higher alkali reading.

Turning back again to my remarks about a possible regeneration due to lime, if this theory were true one should expect to see evidence of it not only in the direct titration method, where in fact it shows us strongly, but

also in the Clennell method if part of the zinc is really eliminated and filtered out as an insoluble compound. I do not see any such indication when the method is carried out strictly as recommended, but when one takes the alkali reading obtained by the other method, which is just as likely to be correct as Green's, and which, after all, is not so very much lower, he gets a value for free cyanide which shows a considerable rise in strength after addition of lime.

In conclusion, I want to make it clear that though for the sake of brevity I have used the term my method in referring to the one I am advocating, I make no claim to connect my name with it. It is as old as the process itself, and its use is almost as widespread. I may sum up what I consider its advantages as follows:

1. I believe it represents the true free cyanide content of a working solution more nearly than any other, except when copper is present in considerable amount.
2. It is rapid and simple.
3. It is definite and capable of considerable precision with a little practice.
4. It is very widely applicable, and the exceptions are few and far between.
5. It provides a simple and rapid method for determining protective alkalinity, as already described, the same solution used for the free cyanide test being titrated direct with standard acid and phenolphthalein indicator.

Of course the most important question in the whole controversy is not, really, how much of the cyanide is free, from an academical standpoint, but how much is available for doing work. There is considerable diversity of opinion on the subject, and many text books treat total cyanide as if it were synonymous with available cyanide. If by available is meant latent cyanide the term might pass, but I very much doubt whether the potassium zinc cyanide can be called available in the sense of being ready to do work without work of some kind being first expended on it. I have been making a few experiments lately to try to throw some light on this point, and if when they are finished they seem to me of general interest I hope to offer them to you for publication.

Before leaving the subject of Mr. Allen's article I wish to point out a misapprehension he has fallen into in referring to the zinc solution at the Nipissing. He quotes the figure given in my paper for the assay of the precipitated solution (0.8 oz. Ag per ton) as if it were a result obtained on a working scale, but I stated that, although zinc precipitation was planned for the new mill it was never used, and the mill was started with the aluminum precipitation.

The solution in question was merely that obtained from laboratory experiments and was run through a small zinc box to remove the silver before being used over again. This box was worked intermittently, and was not tended very zealously, hence the high tailing assay. I see no reason to suppose that had the zinc process been installed in the new mill the barren solution resulting therefrom would have been any higher in silver content than that now obtained by aluminum precipitation.

E. M. Hamilton.

Divisadero, Salvador, C. A., April 23.

Early Leaching Experiment

The Editor:

Sir—From 1895 to 1903 I operated a copper ore leaching plant at Warrior, Arizona, which has since been destroyed by fire. In connection with this there was built and operated an up-to-date sulphuric acid leaching plant with a capacity of about 300 tons ore per day. Up to that time I doubt if a more perfect leaching plant has been in operation in the United States. The copper was recovered by scrap iron, contained in a revolving, perforated, heavy plate copper drum 8 in. diameter and 12 ft. long, which revolved in copper sulphate solution in a lead-lined tank. The copper precipitates were smelted and refined in a reverberatory furnace using oil for fuel and producing copper ninety-nine and eighty-five one hundredths fine. At that time I secured two patents on mechanical appliances which upon practical test helped but little to overcome the difficulties. I discovered that when one makes a solution of, say, one to three-tenths of 66°B. sulphuric acid and from seven to nine-tenths water, the best results are obtained. I extracted about 65% of the copper contained in the 7% ore. In practice I came upon the same difficulties that everyone has and that is leaching the tailing free from almost a trace of copper and which is absolutely necessary in the low-grade ores. Laboratory or mechanical tests, even on ten-ton lots, are of no value and only tend to deceive, as failure will come after a large amount of money has been spent trying to handle a large tonnage commercially. I have since overcome these difficulties by a simple and inexpensive plant, which is automatic in operation and reduces the copper in tailing to a trace. I expect to precipitate the copper, contained in sulphate solution by electricity on cathodes regardless of how impure or foul the solutions may be.

Globe, Arizona, May 26. James A. Fleming.

Siderite and Sulphides in Leadville Ore Deposits

The Editor:

Sir—Through the omission of the words: "Leadville excepted," in paragraph 2, column 2, page 52 of your issue of July 11, I am made responsible for the statement that the occurrence of siderite at Leadville has been described in the U. S. Geological Survey reports; this statement I believe is incorrect, the only reference I find touching the subject being in the nature of a disclaimer and stating the silicate and carbonate of manganese "are notably absent from the sulphide bodies at Leadville" (*Bull.* 320, 'The Downtown District of Leadville,' 1907, p. 34).

In justice to the Geological Survey and to myself, I ask that you publish this explanation.

Denver, Colorado, July 17. Philip Argall.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COST of making gas at the municipal works in Belfast, Ireland, was 24.502c., and the profit 16.218c. per 1000 cubic feet. The output in 1912-13 was 2,480,628,000 cubic feet.

EVERY STEEL TOWER on the Waihi company's new transmission line, 50 miles long from the mine to the hydro-electric plant, is numbered and has a danger notice attached to it. Part of the route is over a range 2500 ft. high.

A RHEOSTAT resistance block consisting of manganese oxide, zinc oxide, silicate of soda, and brass filings mixed together in suitable proportions has been patented by Arthur Illingworth Graham, of Wellington, New Zealand.

BRICK SMOKESTACKS which are cracked or showing signs of weathering, and which it is not convenient to pull down, may be greatly strengthened for many years by pouring about 12 in. of concrete all around the chimney. A frame of light timber is erected to the top of the stack, and concrete elevated by a cage and poured in the forms built around the brickwork, starting from the bottom.

KING-POSTS in a stamp-battery are often thrown out of plumb as a result of the settling of bins to which they are connected, and also as the result of continual vibration. In either case it is preferable to allow them to retain the firm and settled position in which they have placed themselves, rather than to attempt to re-plumb them. The guide-girths and cam-shaft bearings should be shimmed or otherwise altered in order to plumb the stems and level the cam-shaft.

A PROCESS for treating sulphide ores of antimony and arsenic for the purpose of extracting these metals, consisting in melting the ore with sodium sulphate, carbon, sulphide of iron and sodium carbonate to form a sulpho-salt and oxide, removing the slag formed during the melting operation, smelting the sulpho-salt and oxide with iron and carbon, and recovering the sulphide of iron and the sulphide of sodium from the slag formed by the reduction process, has been patented by Alexander Trifonoff and Daniel Gardner, St. Petersburg, Russia.

EARTH TREMORS are increasing on the Rand, according to H. E. Wood, who read a short paper on this subject before the Chemical, Metallurgical and Mining Society of South Africa. Since 1908 there have been the following number of tremors each year: 7, 3, 12, 14, 38, 82, and 15 up to March of 1914. The Witwatersrand tremors are semi-artificial in origin, and the ultimate cause of them is to be found in the extraction of large quantities of rock and water from comparatively small depths beneath the surface. The combined effect of mining and water-pumping operations is to divide up the ground beneath the surface into small sections, which may be subdivided further by existing faults. These small sections gradually become unstable, owing to the withdrawal of their supports, and suddenly slip by small amounts into positions of greater stability. This slipping communicates a slight jar to the surrounding ground, and the effect is radiated as a single wave of small amplitude. There is no evidence to show that this happens only in one particular region of the Witwatersrand, but the localities over which the shocks are felt are found more frequently along the Central and Eastern Rand than along the Western Rand. The existing records do not indicate that the local tremors are more frequent at any particular season of the year, so that it does not appear that their occurrence is facilitated by weather changes, etc. The length of the records is, however, too short to make any definite decision on this point. In the subsequent discussion of the paper, A. C. M. Sim said that earth tremors on the Witwatersrand concern all those who are interested in the industry there, and he had always felt that these earth tremors, which are sometimes attributed to blasting and sometimes reported from the Observatory as earthquakes, are due chiefly to another cause. As is well known, on the Village Main Reef mine there is a line of fissure in the earth, which has caused an extraordinary fault through the three 'reefs' in that mine, and unlike the ordinary faults which occur frequently along the Witwatersrand series. The fissure is very apparent in the Village Main Reef mine, after leaving which it goes right through Lower Doornfontein, and through the Bezuidenhout valley, south of Bedford farm. That means that the whole of the 'Hospital' series are resting on that fissure of the earth's crust, which fissure runs almost diagonally across the reef and up the valley. Therefore, it is obvious, from time to time, as the ground settles, the people who live on the north or northwest of the fissure will feel the shock, and people southeast of it do not feel it to any great extent. Though G. S. Corstorphine makes little mention of this interesting occurrence in his book on the formations and geology of the Transvaal, Mr. Sim stated that the fissure does run through the 'reef' and that is the reason for nearly all of these 'earthquakes' of which so much is heard from time to time in the local papers.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MOTHER LODE DISTRICT, CALIFORNIA

ACTIVITY ALONG THE LODE.—WORK AT MARIPOSA, BIG OAK FLAT, JACKSONVILLE, JAMESTOWN, BLACK OAK, CARSON HILL, ANGELS CAMP, HODSON, RAILROAD FLAT, WEST POINT, JACKSON, PLYMOUTH, PLACERVILLE, AND GRIZZLY FLAT.

During a recent trip which covered fairly thoroughly the Mother Lode and the nearby districts, from Mariposa to Placerville, encouraging activity was noted. Many of the old mines that have been idle for some time past have been reopened under new management, or by lessees, and the general spirit all through the gold belt is one of optimism. A good feature is that considerable prospecting is going on, and where mines are being reopened it is on a conservative scale. The expensive lessons of elaborate surface equipment for an undeveloped mine have been learned, and the tendency is to develop the equipment along with the mine instead of in advance of it.

Mariposa.—This district is handicapped by the fact that many of the best mineral deposits are on the Mariposa land grant, and the managers of the grant will allow them to be worked only on such terms as are generally considered prohibitive. Some copper deposits have been opened east of town, but so far development has not been carried to a point that shows their actual value. At Colorado, the Colorado mine has started with a few men, and the mill is in operation.

Big Oak Flat.—The Longfellow and the Big Casino mines are working and are running mills at both. The Longfellow is doing company work, and the Big Casino is being operated under a lease, dropping ten stamps. East of Groveland it has been the intention to resume work at the drift-gravel mines of Gold Ship Mining Co., but there is no definite news that work has actually commenced.

Jacksonville.—Work has been resumed at the McCormick group on the river. The main adit is being driven around a bad cave, and will be extended to catch the vein that has been opened in the upper workings. The Shawmut is engaged in development work.

Jamestown.—Negotiations were opened in the spring looking toward the taking over of the Rawhide group by Alexander Chalmers and associates. Mr. Chalmers has been superintendent of the Lightner at Angels Camp for some years past, and there is every assurance that if he gets control of the Rawhide it will be worked actively.

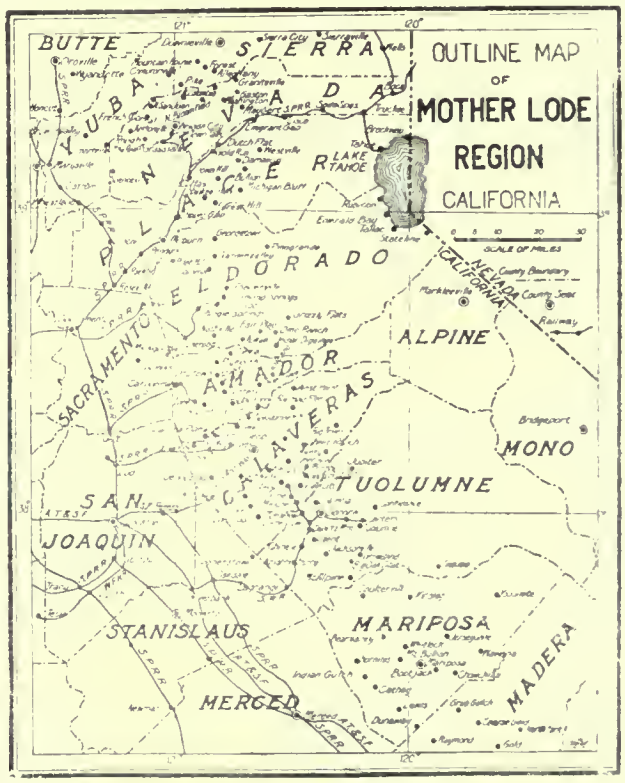
Black Oak.—The Black Oak mill, which is using the cyanide process described in the *Press* in 1912, is a success, and production has been continuous for some time past. The main shaft was recently sunk to the 1770-ft. level, and drifts started both ways from the bottom. North of the Black Oak, the Syndicate, which is controlled by the same interests, has several men sinking the shaft and, to the west, the Draper has been unwatered and is cross-cutting.

Carson Hill.—The South Carolina has started and is running its mill. A leaching plant is being erected near Malones to treat its tailing.

Angels Camp.—The cost of mining the upper levels of the Lightner, where the ground is very heavy and shifting, has proved too high for the grade of ore found, and production has ceased at this mine until the shaft can be sunk further, and new orebodies found on the 1000-ft. level can be developed. This is somewhat offset, however, by the fact that the Johnson, west of town, has been supplied with new equipment and pumped out preparatory to the resumption of operations.

Hodson.—This little camp, two miles west of Copperopolis, will see active mining for the first time since the Royal was closed down some years ago. The litigation and financial troubles of this mine have been disposed of and preparations are under way to resume production. Copperopolis is quiet except for keeping the Calaveras Copper Co.'s mine unwatered, and doing a little precipitation of copper from the mine waters. It is notable, however, that the Company will not talk lease to anyone, and it is rumored that efforts are being made to relieve the financial trouble so as to open the way toward the resumption of operations.

Railroad Flat.—The Comet, north of town, is operating in a small way, efforts at present being confined to sinking the main shaft. The Mohawk, formerly the Keystone, east of town, has been taken over by lessees. The shaft is being cleaned out and retimbered, and some ore is being extracted.



West Point.—After considerable development work a small mill will be built at the Lockwood. Across the river, at Defender, O. E. Lofstad has built a new head-frame, and has ordered hoisting equipment for his claims. Sheridan Barnhart has opened a good vein near the Defender mine.

Jackson.—The long drawn out suit between the Kennedy Extension and the Argonaut has been decided in favor of the latter. The general sentiment is that the decision of Judge Wood was just and that, as the principal litigant is dead, the case will not be appealed. This relieves the uncertainty under which the Argonaut has been working for some time past, and puts it in a position to go ahead on a larger scale, which it is expected will be done.

Plymouth.—The Pacific mine is building a fine equipment. A 30-stamp mill, with Hardinge mills for regrinding, is nearly completed, the head-frame has been enlarged, new hoist installed, and haulage system and completely equipped shops are

being built. This mine should be in operation in the early fall, and will be one of the best equipped on the Mother Lode.

Placerville.—Practically nothing is being done here in the mining line except at the Pacific, where diamond-drilling is being carried on underground to prove the orebodies before resumption of active operation.

Grizzly Flat.—The Mount Pleasant is the only mine that has been operated here for some time past, and that only in a desultory sort of way. A five-cent assessment has been levied and is coming in quite satisfactorily. It is hoped thereby to obtain sufficient money to clear-up outstanding obligations, and put the mine in shape to earn the cost of a new mill. The ore is not amenable to treatment in the mill on the ground, and heavy losses have been the result. It is similar to that found at the Black Oak, and it is desired to erect a cyanide plant modeled on the general lines of the one that has been in successful operation at the latter mine.

No mention has been made of the regular producers which are in operation all along the Mother Lode. The Lightner is the only one to drop out of the list within the past few months. The general awakening of interest in mining and the conservative spirit in which most of the new enterprises are being undertaken gives much encouragement to the belief that this district will see a marked increase in production in the near future.

SAN DIEGO, CALIFORNIA

THE OLD JULIAN DISTRICT: GEOLOGY, GEMS, GOLD MINES, AND REASONS FOR MINES SHUTTING DOWN.

The construction of a railroad eastward from San Diego, to connect with the Southern Pacific at or near Yuma, Arizona, is beginning to attract attention to an old and interesting mining district in the Cuyamaca mountains, 60 to 75 miles northeast from the city of San Diego. The district first came into notice following the discovery of rich ore there by a party headed by Mike Julian and the Bailey brothers in the fall of 1869. This district, at first called the Cuyamaca, soon came to be known as the Julian, and a prosperous town of the same name was soon built there. Rich ores were discovered at numerous places in the vicinity of Julian and southeast for several miles, and a second village was built four miles from Julian, known as Banner.

The geological formation for many miles in every direction from Julian is mica-schist and mica-slate, with occasional irregular areas of granite. There are numerous dikes of diorite, norite, diabase, and other basic rocks; but the most important of the dike rocks are the pegmatites, which are not only numerous, but often contain gem minerals, and these have been mined extensively.

The principal gem minerals found are the red and green tourmalines, but topaz, beryl, and other varieties occur.

Gold, however, is the most important commercial product of the region thus far mined there. What the total production has been it is impossible to say, but it amounts to several million dollars. The most noted mines of the earlier days were the Golden Chariot, a few miles from Banner; the Ready Relief, at Banner, which in some respects was a remarkable property; the Washington, Owens, High Peak, and Helvetia, near Julian; the Cable, Cincinnati Belle, Warlock, Kentuck S., Antelope, Ella, and numerous others between Banner and Julian. The largest mine in the region was the Stonewall, about 12 miles south of Julian. This mine was the deepest, about 600 ft., and had the most complete equipment of any of the properties. It was at one time a large producer. Other districts in the region were Mesa Grande, Pine Valley, and Boulder Creek. The ores of the entire country around have a marked similarity, being free-milling quartz which mostly occurs as lenses in the schists and slates, that in the granite having more the usual characteristics of fissure veins. The quartz is often surprisingly rich in gold, but the ore-shoots proving erratic, the miners seldom had either the inclination or the means to carry on systematic development in advance of the extraction of the ore. The usual result has followed this too common policy—numerous idle mines with little incentive for the owners to carry exploration work beyond the face of a pinching shoot of ore. However, the rich ores for which the region has been noted, and the possibility of discovering new and profitable shoots in these old mines, both in greater depth and longitudinally, will probably act as a stimulus to newcomers, who are certain to now invade the old district with the advent of the railroad. It is not in the least unlikely that this region, a famous producer of high-grade ores 30 to 50 years ago, will soon once more contribute substantially to the gold output of California. Some years ago not less than 20 mines were in opera-

MAP OF SOUTHERN CALIFORNIA.

tion in the Julian and Banner districts under a system of leases, but as the lessees were men of small means the net results were little, if any, better than when the mines were operated by the owners. The causes for failure of many of these mines may be summed up in the following: small scale operations due to lack of capital; expensive transportation and milling charges; a lack of knowledge of the best methods of mining and metallurgy; poverty or extravagance on the part of the operators, usually both, and consequent inability to carry development ahead when the end of an ore-shoot was reached.

TORONTO, ONTARIO

CANADIAN GOLD FIELDS, LTD.—BAILEY COMPANY'S AFFAIRS.—CHAMBERS-FERLAND PROPERTY.—CANADIAN IRON CORPORATION REORGANIZATION.

The Canadian Gold Fields, Limited, the chief asset of which comprises stock in the Consolidated Mining & Smelting Co., is taking steps to distribute this stock among the shareholders of the holding company, the exchange to be on the basis of one share of Consolidated for every 1500 shares of Gold Field. After this distribution, there will be 270 shares of Consolidated left, which will be sold for cash and the proceeds distributed.

In connection with the liquidation of the Bailey company,

as decided on by the directors a short time ago, official action has been taken by the Standard Stock and Mining Exchange. The Exchange has departed from its ordinary custom and has asked for proxies to contest the action of the directors in liquidating the Bailey company. The president of the Exchange states that he is unable to explain the proceedings for the winding-up of the property, and on inspecting the records finds that Edwin A. Benson, the president, and other promotors issued 4,250,000 shares of $1 par to themselves, leaving only 750,000 shares in the treasury for the financing of the property. In 1909, Benson was the registered holder of 2,155,165 shares, and his interest has steadily declined until the present time he is the registered holder of only 278,190 shares. Other promoters who held large blocks of stock have also been selling in the same way, while the 750,000 shares in the treasury has been held. It is thought that this treasury stock was not sold as it might have come in competition with the promoters' shares, and the result has been that the public now owns practically all the property, without any of the money realized for the sale of shares having gone toward the liquidation of its debts or the financing of its undertakings. If the Exchange receives a sufficient number of proxies before the petition for the winding-up order comes on for hearing, counsel will be engaged to oppose the petition, and to challenge and dispute the validity of the judgment.

It is probable that some definite action will at last be taken regarding the disposal of the Chambers-Ferland property, which has been so strenuously opposed by the minority shareholders during the past few months. The fight is with reference to the proposed by-law for the transfer of the entire stock and assets of the Chambers-Ferland Mining Co., and 150,000 £1 shares in the Aladdin Mining Co. This latter Company already holds a majority interest in the Chambers-Ferland, and the directors are desirous of obtaining the control of the entire property. The minority shareholders, however, claim that the directors are trying to force through a deal prejudicial to their interests. The only assets of the Aladdin company is a lease on the old Silver Queen mine, and a small amount of cash in the treasury. The Silver Queen was originally abandoned as being worked out, and while some small amount of ore has been found, possibilities for the discovery of any considerable bodies of ore are doubtful. On the other hand, the Chambers-Ferland has liquid assets of $150,000, 124 acres of mining property and ground rentals totaling $6000 per year. The mine has been worked for some years, and while it has not paid any dividends, is supposed to be making a certain amount of money. On account of its location, adjoining the Nipissing and La Rose, the undeveloped territory offers considerable promise for the discovery of new orebodies. The minority shareholders claim that the Aladdin Mining Co. wishes to transfer the assets of a working property of considerable promise for stock, in a company having practically no assets, and they intend to take advantage of the new amendment to the Ontario Companies' Act, passed at the last session of the legislature, which covers such cases. One of the directors has also applied for an injunction to restrain the passing of the by-law for the sale of the property. A further meeting of the directors was called for July 1 in London, but so far no information as to what has taken place is available.

At a recent meeting of the bondholders of the Canada Iron Corporation, which went into liquidation a few months ago, the proposed reorganization was formally approved. The measures adopted by the bondholders provide for the cancellation of the existing trust deed, and the acceptance by the first mortgage bondholders of 6% debenture stock, to be known as 'B' stock in a new company, the exchange to be on the basis of par for par. Prior to this security will be an issue of 'A' debenture stock of an authorized amount of £200,000, of which not less than £120,000 and no more than £140,000 will be subscribed for at 95, to provide the necessary cash for working capital. Preferred and common shares will also be issued, the amounts of which will be determined after negotiations with the second bond holders and holders of secured notes and other creditors of the old corporation. The old preference and common stock will be wiped out, but shareholders who subscribe to the 'A' debenture issue will be given a bonus on the new common stock, which may, in the event of the reorganized company proving successful, help to offset their loss.

JUNEAU, ALASKA

EARLY MINING AROUND JUNEAU, AND FUTURE TONNAGE.—WORK AT THE ALASKA JUNEAU, TREADWELL, EBNER, JUALIN, PENN-ALASKA, TREASURE, AND OTHER PROPERTIES.

To the Juneau district is credited the first gold production of the territory of Alaska. According to a statement of Eugene Owens, a mine owner of Sumsum, Alaska, to the U. S. Geological Survey, the Windham Bay placer diggings produced $40,000 in 1870-71. The first real prospecting in what is the Juneau district was done in 1880 by Joe Juneau and Richard Harris, sent from Sitka by N. A. Fuller. They found placer gold and quartz veins, and returning to Sitka with 1000 lb. of ore, started a small rush. The next year saw considerable prospecting in the district. In the fall of 1881, a village at the foot of Mt. Juneau, called Harrisburg, had a population of 100. The name later was changed to Juneau. Placer mining at first occupied all of the attention of the miners, and in some cases hindered the development of quartz properties. On Douglas island, opposite the mainland from Juneau, the Treadwell claim was being developed in 1883 with the aid of a five-stamp mill. Aside from desultory prospecting on quartz veins in Silver Bow basin, near Juneau, the Treadwell represents the first quartz-mining operations in the district. More prospecting was done between 1883 and 1885, and in the ten years to 1895, most of the principal properties in the district were patented. Careful treatment of ores became necessary when the veins were discovered to be of low-gold content. The Treadwell company's first mill had 120 stamps; its present mills containing 540 stamps. Work in progress on the Alaska Gastineau, Alaska Juneau, and Alaska Ebner properties, all on the mainland, leads to estimates of a future daily capacity for the mills of the district of 25,000 tons, to be realized within four years. The present payroll of the mines in the immediate vicinity of Juneau amounts to $350,000.

Cross-cuts are being driven from the main raise which connects with the 6538-ft. adit on the Alaska Juneau holdings. A crew is at work, developing the mine to that stage where additional units of milling equipment may be installed. The vein, where cut by the main adit, has a thickness of 500 ft., with ore assaying $2 per ton. Forty stamps of the first of four 150-stamp units of the proposed milling equipment are in continuous operation on the property. Ten of the stamps are used as a pilot plant, the operation of which will determine largely the method of treatment for the first unit as well as subsequent units. Two hundred tons per day is crushed by the pilot plant. F. W. Bradley, president of the Company, estimates mining costs at the Alaska Juneau at 40c. per ton, compared with 95c. at the Treadwell, and milling costs at 20c. compared to 25c. at the Treadwell. When the installation of the proposed four units is completed, which will be in about four years because of the great amount of development necessary in the mine, the Alaska Juneau will have a capacity of 12,000 tons per day. A statement issued by Mr. Bradley shows that the plans of the Alaska Juneau company will be carried out as originally announced, despite rumors that the work was about to cease. "Everything will progress as originally planned," said Mr. Bradley, "but of course we cannot build any

more mills until there has been considerable more mine development." The contracts have been signed for machinery for the Alaska Juneau and Treadwell companies, aggregating a quarter of a million dollars in cost. The Charles C. Moore company, of San Francisco, gets the contract for increasing the capacity of the steam power-plant at Treadwell, on the opposite side of Gastineau channel from the Alaska Juneau holdings, from 3000 to 7000 kilowatts. The first unit is to be completed in six months and will increase the plant's capacity to 5000 kilowatts. The second unit will be added next year. Contracts also were signed for an Ingersoll-Rand 40-drill compressor, operated by a General Electric induction motor. Because of the announced policy of this Company to refrain from going into the boarding house or store business, its standing among the residents of Juneau is high. Nearly 2000 men will be employed eventually, and as the mill and entrance to the mine are virtually within the city limits, the townspeople of Juneau will derive the benefit.

The Treadwell mines still are the largest operators in the district. With the completion of the central hoisting plant, with its Nordberg hoisting equipment, plans are being hastened to hoist the ore of the Alaska Treadwell, 700-Ft., and Mexican claims through the central shaft. The first Alaska Mexican ore will be hoisted within two months. The hoist operates 11 hours daily, raising 3500 tons of rock. All ore to the east of the central plant on the Treadwell lode eventually will be hoisted through the 2200-ft. vertical shaft. On the 2100-ft. level of the Alaska Treadwell, 1500 ft. of adit has been driven and driving is now going on. Stoping will start next winter. Plans are being considered by the Treadwell company to increase the capacity of the Nugget Creek power-plant to 12,000 hp. The present and proposed steam equipment will then be used as an auxiliary plant. The new operations in the district have necessitated careful consideration of power plans.

The Ebner property is being developed by the United States Smelting, Refining & Mining Co., which has also taken options on the Hallam and Dora groups, adjoining the original Ebner claims on the northeast. It is current in Juneau that they have optioned from George R. Noble the Boston and Boston King groups, as well as the Epstein, Goldstein, and Wagner-Folsom properties, with a view to consolidating and development on a big scale. The Ebner property is being developed with a long adit from Silver Bow basin, as at the Juneau.

A proposed 8000-ft. adit on the Jualin property, north of Juneau, on June 19 was in 991 ft. The adit is 7 by 8 ft. in the clear. Progress is being made at the rate of 450 ft. per month. The Company is employing 125 men. The monthly payroll amounts to $25,000. Ingersoll-Leyner water type drills are used in the work. The Jualin property is owned by Herbert L. Hoggatt and is under bond to the Algunican Development company, a Belgian syndicate. A small stamp-mill is operated on the claim. A Pelton water-wheel furnishes power. A new wharf has just been completed. Material for a wireless station at Jualin is now on the ground.

In the Berners Bay district, many promising properties are undergoing constant development. Among them is the Frank Fremming property, immediately adjoining the Jualin and the Kensington, in which the Alaska Gastineau company has a share. The Greek Boys property at the mouth of Berners river is being opened up. The Eagle River mine is being developed under B. B. Naeding. In Montana basin there is considerable prospecting. H. R. Plate, representing a Canadian syndicate, has taken options on a number of claims in the Auk Bay district and is engaged at present in supervising the development work on the claims.

At Taku inlet, southeast of Juneau, the Penn-Alaska Mining Co. has 21 claims which it is developing. Ground has been stripped for an experimental mill and water rights have been staked. A small power-plant has been installed. The Company also holds four claims lying northeast of the Alaska Gastineau holdings.

The Alaska Treasure Co. has optioned a number of claims on Nevada creek and is planning the development work on the ground. The Jersey City group, consisting of seven claims one-half mile southwest of the Alaska Treadwell glory-hole on Douglas island, and owned by M. J. O'Connor and associates, has been optioned to Walter J. Brocking and Mr. Armstrong, who expect to begin work soon. A shaft has been sunk 75 ft. and drifts run a distance of 80 ft. on a vein of free-milling gold ore 25 ft. wide. The ore averages $4.85 per ton and has been traced for 3000 ft. The work this season has shown up another vein with a width of 600 ft., carrying ore on the surface, where disclosed by stripping operations, which assays 90c. per ton.

MILL AT THE EBNER MINE.

ALASKA JUNEAU 40-STAMP MILL.

NEW YORK

ATTITUDE OF EASTERN CAPITAL TOWARD MINING MEN.—WORK IN MEXICO.—UTAH CONSOLIDATED.—BUTTE & SUPERIOR.—ELM ORLU SUIT.—W. B. THOMPSON'S RISE.—COPPER STATISTICS.

A peculiar situation exists in New York in regard to mining properties. There is a demand for developed or producing properties, but despite some notable examples of mining successes, it is almost impossible to induce the Eastern investor to become interested in anything that has not already shown itself a profit-earner. The exploration company, which has been so much of a progressive factor in English mining interests, has never appealed to American capital to anything like the extent that it should. The field has been so largely left to a few concerns, that today when some Western mining man comes to New York for assistance in developing or to sell claims, he is mystified to find that after visiting one or two offices he will find the details of his property ahead of him in any other quarter that he may present it. It is a most familiar thing to hear them say they had thought New York to be a big city, only to find it apparently smaller than the mining camp they left behind them in so far as the traveling of news is concerned, and the number of people with whom it might be possible to do business. Yet everyone familiar with the situation will say that real mines can be readily sold in New York. At the bottom of this state of affairs lies an undue degree of timidity, both on the part of the public and the engineers to whom they look for guidance. This is the complaint of the laymen, that there is no willingness to take the legitimate chance which is necessarily a part of mining success, that the engineer should not so greatly fear any penalty for favoring development that promises well, and should see that no good possibility or probability gets by his clients, rather than to fear that he may lose prestige by recommending expenditure that may not prove profitable. Numerically, failures must be greater than successes, and it is to meet this condition and cover this hazard that is the office of the exploration company. The centres of accumulated capital in the United States have too few of them; the present number is so small that in New York or Boston the rejection of a property by any one of the half dozen or so possible buyers discredits it more than it should, and a second presentation can only be made at a considerable disadvantage. Under these circumstances it is most natural that these same buyers should realize their control of the market and should, quite without concerted action, eliminate anything like active competition. Mining profits lie largely in successful development, and it is in this development, rather than in operation pure and simple, that the public would like to participate. There lies in this situation a part of the mining field that is not properly occupied. The matter is one of viewpoint or mental attitude, perhaps, more than anything else, but the condition is one concerning which both property owner and investor have some just cause for complaint.

Speaking of complaints, there has been little else heard in that district at the lower end of Manhattan Island known as 'South of Fulton street' during the past week. The pent-up wrath of the public at some of the misdoings in high finance took concrete form in a report of the Interstate Commerce Commission concerning New England's transportation lines, the New York, New Haven & Hartford railroad and its subsidiaries, with the result that the railway shares have been much demoralized, the market drop occupying the centre of the stage to the exclusion of nearly all other features that ordinarily come in for some share of public attention.

The progress made in Mexico ought eventually to have a good effect on the mining interest of the East. The opening of new fields or getting back into old ones with improved prospects would be a considerable help in securing and holding public attention. Affairs like the shutting down of Greene Cananea, where labor conditions became so disturbed as to force the management to prepare for an indefinite period of idleness, do not make for present enthusiasm over Mexican mining operations. Not all American mining progress has come to a complete standstill, however. H. Vincent Wallace, who is directing the operations on the Nueva Luz cross-cut at Guanajuato, has remained continuously on the job and has been making some progress toward the extension of the Valenciana, which it is hoped will be opened at depth. At the Santa Gertrudis property the manager, H. Rose, has remained in charge, and while it has proved impossible to keep the mill going, the mine has been under development. The Grenfell failure in London touched the Sta. Gertrudis, but has not affected it seriously.

It is said the Utah Consolidated management is actively engaged in a search for a mine to take the place of its Bingham property. Mark L. Requa and Roscoe H. Channing have been making some preliminary field surveys in Nevada, without, however, finding anything among those properties looked at sufficiently developed to permit of actual examination.

N. Bruce MacKelvie, of the firm of Hayden, Stone & Co., Kurnal Babbitt, and D. C. Jackling have all been at Butte in conference with W. A. Clark concerning matters in dispute between the Butte & Superior company and the Elm Orlu mine owned by Mr. Clark. Mr. MacKelvie is the president of the Butte & Superior, while Mr. Babbitt is the legal representative of the Hayden-Stone, Shove-Aldrich, Jackling-Penrose, MacNeill interests, which include, with the Butte & Superior, Chino, Ray Consolidated, Alaska Gold, being enough to swamp any organization not headed by such great workers.

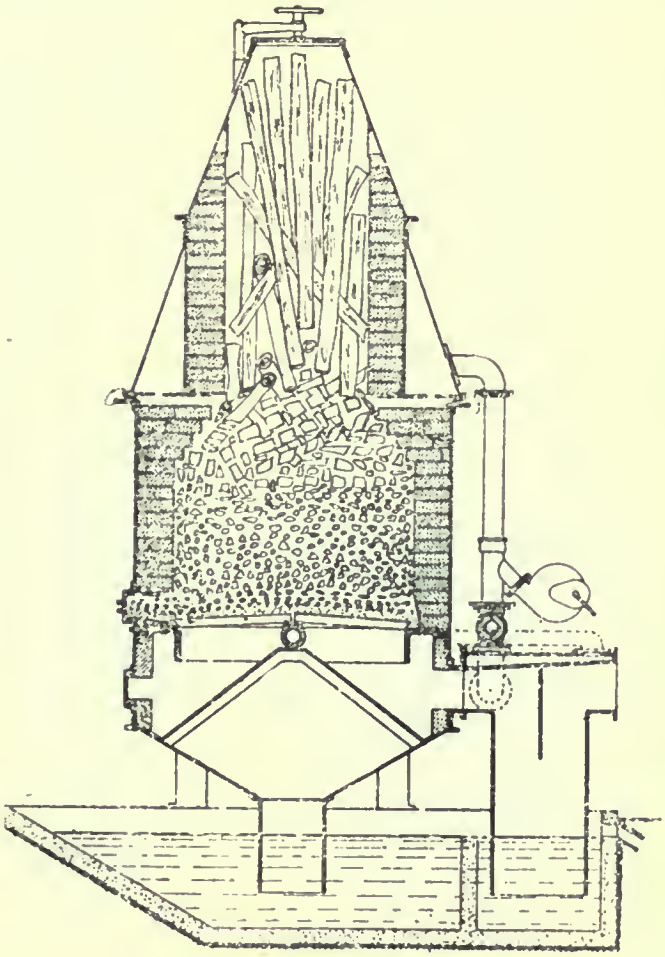
William B. Thompson, whose rise has been so rapid since he came to New York from Butte some years ago, is apparently about to step from a leading place in mining circles to an equally prominent place in the banking world, being the leading candidate for one of the directorships of the Federal Reserve Bank of New York. Mr. Thompson has been the leading spirit in several successful mining enterprises, including the old Cumberland Ely, since merged into Nevada Consolidated, this interest placing Mr. Thompson in the directory of the Utah Consolidated, including also Nipissing, La Rose, and, later, the Mines Company of America, Mason Valley, and Inspiration.

The porphyry properties are now making up figures covering production for the half-year, and so far show increases in tonnages handled, lower costs, and improved results. It is hard to realize or estimate just what the copper mines of this country could do if under pressure of normal demands from consumers. The export trade seems fated in some way to take the best of the copper market's ups and downs. Foreign deliveries for the six months just passed about 13% greater than for the same period last year, the average monthly shipments being 81,700,000 lb., against 72,400,000 lb. in 1913. Domestic deliveries were 55,000,000 lb. monthly as compared with 64,000,000 lb. for the half-year ended June 30, 1913. While one may lament the fact that the foreigner seems to secure an undue share of our cheap metal, the really significant feature is that record production—835,137,652 lb. for the six months ended June—has not built up any surplus of any consequence. Every report of conditions abroad speaks of depression. Our own situation is best shown by the fact that our percentage of domestic consumption dropped from 46% in 1911 to 39% for the first half of the current year. What will be the result when domestic conditions are good again? Evidently the country will need all that the Inspiration, Braden, Chuquicamata, and other great mines can turn out. Miami produced in the half-year 20,043,056 lb., against approximately 16,000,000 lb. during the same period last year. Braden turned out 12,451,000 lb. for the six months' period, but material increases are expected in each month's output during the remainder of the year.

KALGOORLIE, WESTERN AUSTRALIA

SUCTION-GAS PLANTS AT SONS OF GWALIA, LANCEFIELD, AND CHAFFERS MINES.—GREAT FINGALL MINE.—LABOR TROUBLES.—LAVERTON DISTRICT.

The whole of the treatment plant on the Sons of Gwalia mine, after being thoroughly overhauled and brought up to date, is being driven by two Crossley gas-engines of 400 and 167 hp. respectively, and one Kynoch engine of 660 hp. The gas is generated by three Commonwealth down-draft gas generators of 380 hp. each, burning *mulga*, a local wood of high heating value, in 5-ft. lengths. After overcoming some trifling



SECTION OF COMMONWEALTH GAS PRODUCER.

initial difficulties, these generators are proving so successful that the plant runs a full month without a stop. The saving of firewood when gas engines are used is 7000 tons per year, or $21,840, taking firewood at $3.12 against charcoal at $14.16 per ton, in the proportion of 172 tons wood to 100 tons charcoal, comes to $1152 per month, and the running is more regular. After watching the operation on the Gwalia mine, the engineers of the Kalgoorlie & Boulder Firewood Co., which now owns the Lancefield mine, and supplies the firewood to the Sons of Gwalia mine, have ordered three 250-hp. Commonwealth generators for the Lancefield, and the management of Chaffers has also ordered one of 380 hp. These generators are also in use at the Yuanmi and Queen of the Hills mines, where they have replaced charcoal generators. No suction-gas plants have been installed on any of the large mines at Kalgoorlie.

The Great Fingall company, which for the last five years has been opening the new ore-shoot discovered by sinking an internal shaft at a point 900 ft. north of the main shaft at No. 13 level, is about to start breaking ore from this body. The lode at No. 15, 16, 17, and 18 levels has had the leading stope started, and 24 machine miners have been sent up from Kalgoorlie to start work. The shoot at No. 15 is 180 ft. long, and assays $10.46 per ton for the width of the drift, 72 in.; at No. 16 it is 252 ft. long, and assays $10.62 per ton over 72 in.; at No. 17 it has been proved for a distance of 300 ft. to assay $9.60 per ton for the width of the drift; and at No. 18 level assays average $11.16 per ton for a length of 533 ft. Winzes sunk below No. 18 level show ore assaying up to $31 per ton. As in the upper levels, the lode bulges in places up to 40 ft. wide, but the full extent will only be disclosed in stoping. During the past 16 months the Company has worked at a loss of $72,000, including capital expenditure, and paid a dividend of $62,500 out of reserve funds, thus reducing the reserve to $218,700. H. P. Woodward, government geologist, in 1909, and Malcolm Maclaren in 1910, advised the management to continue sinking through the barren zone with the above result. It is interesting to recall that Mr. Woodward, in his handbook published 20 years ago, in 1894, stated that "This line is called the Day Dawn, and is a true fissure vein, but does not follow any definite course; but this is not of the least consequence, as, from its well defined walls, there is very little chance of it cutting out." In spite of that, the mine was abandoned on the first lens cutting out before the Great Fingall acquired the mine in 1899. Prior to that it had produced 30,000 tons returning $375,000 at a loss; and, since then, another 1,836,400 tons for a yield of $23,336,500, and paid dividends aggregating $8,734,000. The first lens pinched out at a vertical depth of 150 ft., and the ground was barren down to 460 ft., when the second lens, which has produced all the wealth and dividends, was encountered, and cut out at No. 13 level.

Labor troubles in this state still continue. Laborers on the Trans-Australian railway are still on strike, as their leaders insist on their receiving $3.20, and refuse to allow a ballot to be taken regarding the federal government's offer of $3, and to leave the arbitration court to fix a rate to be retrospective. All the builders, carpenters, etc., on the coast are now out, as the union men employed at Millar's sawmills absolutely refuse to work with three non-unionists, and the strike has spread to Perth and Fremantle, as the employers will not yield. The Australian Labor Federation has not yet made up its mind whether to insist on non-unionists in the goldfields being dispensed with, as the Chamber of Mines has frankly stated that it will close down every mine in preference to being dictated to by the labor unions. The deadlock shows no signs of reaching a conclusion.

Early in June the announcement was made that the Melbourne directors of the Mary Mac company, which holds a lease called the Lady Harriet, at Laverton, had bought out the tributers, Tasker and Hunt's interests for $60,000 cash and 4000 fully paid shares. In January, 1913, the Mary Mac company acquired the lease, and erected a hoist, boiler, headframe, 10-stamp mill, and cyanide plant, driven by a suction-gas engine. The first clean-up in November yielded $2000 from 1200 tons, or $1.67 per ton. The mine was then let on tribute for two years at 12½% royalty. Up to the end of April the tributers treated 2976 tons for $11,700, and paid the Company $5200 in royalty, besides clearing a profit of $25,000. The lode is in a hill about 60 ft. high, in which an adit has been driven and the ore is being mined over a width of 80 ft., and drops into the adit through passes for delivery to the mill. Included in the purchase is a claim on each end and one on the side. Thirty more stamps are to be added to the equipment, and a profit of at least $25,000 per month is expected. The Lady Harriet, previously known as the Enniskillen, is on the main line of lode at Laverton, which includes the British Flag, Union Jack, Pinnacles, and Craiggiemore, all first worked 15 or 16 years ago, and most of them abandoned for a dozen years. The Craiggiemore, between 1899 and 1906, produced 105,700 tons yielding $750,000, and was then abandoned.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

When all the survey parties are arranged, there will be 11 outfits in the field for the United States Government railroads, each with a certain section, as follows: Fairbanks to Nenana, Fairbanks to Healy crossing, Nenana to Broad pass, Broad pass to Susitna, Susitna to mouth of Matanuska, Matanuska to Turnagain arm, Turnagain arm to Seward, Turnagain arm to Portage bay, Chitina to Matanuska coalfields, Mile 140 on the Alaska Northern to Matanuska, and reconnaissance survey from Susitna to Matanuska river.

Chisana

According to G. E. Vergowe, who arrived at Cordova during the last week of June, there are 300 people at Chisana, of whom 180 are miners employed on the various claims. On June 16 about 115 men formed the Shushanna Miners' Association. Most of the operators were paying $6 per day with board, excepting F. T. Hamshaw, who paid $5. His men struck, but returned on payment of the $6 rate. Mr. Hamshaw has made the first clean-up of the season on Eldorado creek, 2700 ft. along bedrock yielding about $4300. There are a few other promising claims. There is not enough employment for all the men now in the camp, and outside papers should publish warnings not to come in. The mail service for letters and papers, etc., is good, there being two mails each way per month.

Valdez

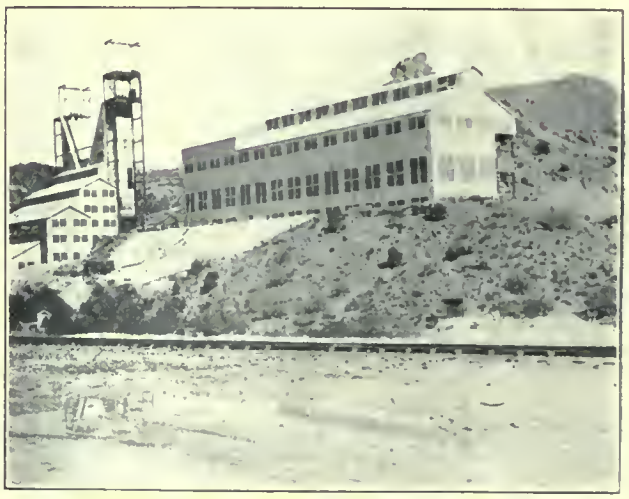
(Special Correspondence.)—Reports here at Valdez are that Frank G. Manley and J. J. Price, who took options on the discovery holdings of the Chisana last fall, have sent in an engineer to Slate creek to make arrangements for a hydraulic project that would embrace the entire creek. Options have been secured on half of the creek already, with the exception of the Miller holdings. George Sias, manager of the Valdez Creek placer mines, left Cordova on July 6 for Valdez creek, by way of Chitina, to inspect the operations on the Company's claims. The new company has acquired control of the original Monohan claims, the Kain holdings, and the Valdez Creek Placer Co. and Valdez Creek Mining Co. The last payment was made January 1, 1914. A pipe-line is being installed under the supervision of Alfred H. Bryant, to take the water of Valdez creek and use it to operate three No. 4 giants with 6-in. nozzles, and one No. 3 giant with a 4-in. nozzle. When complete, the plant will be able to move 10,000 yd. of gravel per 24 hours. Late in 1913 a temporary plant was used to clean about 20,000 sq. ft. of bedrock on the lower part of the claims. The 'dirt' averaged $2.70 per yard. A Pelton wheel of 28 hp. furnished power for two prospecting drills, an electric compressor, a sawmill with a capacity of 5000 ft. per day, and an electric lighting system. The water for operations will be carried 6200 ft. by ditch, and from that point 1000 ft. of 36-in. pipe, 1000 ft. of 30-in. pipe, 1000 ft. of 24-in. pipe, and 1000 ft. of 22-in. pipe will carry the water to the nozzles, with a head of 350 ft. The installation of the present equipment is being made at the suggestion of Forbes Rickard, who completed an examination of the property in 1911. John Carlson is operating on Lucky gulch, a tributary to Valdez creek near its head. His holdings recently were assembled under the incorporation of Lucky Gulch Mining Co., which has headquarters at Fairbanks.

Valdez, July 8.

ARIZONA

Gila County

(Special Correspondence.)—On July 15 the upper 400 ft. of the main east shaft of the Inspiration mine was completed, there being 40 ft. remaining to be concreted in the main west shaft. The lower 200 ft. will be concreted as soon as guides and lumber have been fixed. The fourth and last compressor foundation in the compressor and hoist-house was poured last week. Work on the conveyor system is being hurried along. A 36-in. Overstrom fine crusher is being tried in the test mill. This machine depends for its grinding action on impact alone. It consists of an impeller revolving at 1800 r.p.m., and an annular die against which the ore is thrown by centrifugal force. The coarse ore, averaging 1½ in. diameter, is led into the top of the machine, is caught and hurled against the die with a velocity of about 18,000 ft. per minute. The design of the machine allows no choking, and the capacity



HEAD-FRAMES WITH HOIST AND COMPRESSOR-HOUSE OF INSPIRATION CONSOLIDATED, MIAMI.

is limited only by the power of the driving motor and the rate at which the ore can be fed. It is claimed that it will be possible to handle 40 tons of ore per hour with the machine now being tested at the experimental plant. Several kinds of oil are being tried in the flotation plant.

At the International smelter site, the Short Co. of Chicago, which got the contract from the Oscar Daniels Co., is erecting the stack. The first 100 ft. will be lined with brick. Bedding bins are complete. Stirling waste-heat boilers are being built in. Foundations for five 20-ft. Wedge roasting furnaces are being poured. Those for the engine-house machinery are finished.

Miami, July 16.

The Iron Cap company mined 718 tons of ore in May, yielding 109,759 lb. of copper. The revenue was $9655, and expenditure $8914. During the first five months of the year the respective totals were 3536 tons, 522,733 lb., $52,165, and $39,825.

Seventy-five miles northwest from Globe, in the Mazatzal mountains, H. H. Bowman has discovered a large deposit of cinnabar.

YAVAPAI COUNTY

It is probable that the new United Verde smelter being built for W. A. Clark will receive custom ore when finished.

CALIFORNIA

The Industrial Accident Commission has just made its second quarterly report to the governor, covering the operations of the State Compensation Insurance Fund during the period from April 1 to July 1. The total number of registered applications from employers has now reached 4417, and the estimated annual earnings of employees covered by state insurance is $50,000,000. The total premiums written amount to $379,400. Claims paid, in process of payment, and liberally estimated cost of accidents reported, total $67,122. Total expense, including all items other than compensation payments, amounts to $27,054, or only about 7.1% of the premiums collected. The accrued interest on funds invested amounts to $4550, and the actual balance of the fund now available, including appropriation of $100,000, amounts to $419,098. In addition, a special appropriation of $70,000 is available for contingent expenses of the State Compensation Insurance Fund. This latter amount is not shown in published statements, as there is now no likelihood of the necessity of its use arising. The total number of claim cases handled for the first six months is 1415, and only seven hearings have been applied for to the Industrial Accident Commission. In most of these cases, hearings were necessary to settle complex questions of dependency and to determine the extent of permanent disability.

AMADOR COUNTY

The Argonaut Mining Co., of Jackson, has just declared a dividend of $1.50 per share, amounting to $300,000, and reports an earned surplus of $641,000, or approximately 64% of the entire capital stock, with profits for the first six months of the present year in excess of $150,000, or at the rate of 30% per year. Litigation with the Kennedy Extension cost $113,000, but the above surplus was earned in spite of this suit. The mine is looking at its best, and 4050-ft. level just opened is showing average-grade ore. Jesse Lilienthal was elected president of the Company at the meeting held in San Francisco this week. E. A. Stent is secretary and treasurer.

BUTTE COUNTY

San Francisco men, C. J. Berry, W. W. Johnson, and H. G. Peaks, have bonded the Hupp property near De Sabla. A right-of-way was secured through the old Indian Spring mine 5000-ft. adit for drainage purposes. The adit has been cleared and retimbered for 2000 ft. E. T. Barnette is in charge.

ELDORADO COUNTY

The Plymouth Consolidated company under J. H. Collier is developing the Montezuma mine near Nashville.——The Shaw mine plant, near Eldorado, is to be operated by electric power.

INYO COUNTY

The Wilshire Bishop Creek mine has been unwatered in a week, against 10 weeks in 1913. Development is under way, and the cyanide plant will be erected at once.——Lessees at the St. Ives mine, 25 miles northwest of Bishop, have about 850 tons of $16 gold ore. A Telrault mill, made in Tonopah, is to be installed.

NEVADA COUNTY

Through complaints of Auburn people, Placer county, the Anti-Débris Association is investigating the muddy condition of the Bear river, and hydraulicking at You Bet is under surveillance.——E. C. Klinker has resigned from the management of the Eagle Bird mine at Maybert to look after the Meister claims. H. S. Mourning takes his place.

SIERRA COUNTY

The new mill at the Mexican mine is crushing good ore. If Phelan Bros.' claims are leased the lessees will move an 8-stamp mill from Sierra City to Slug cañon.——A 3000-ft. adit has been started by the Bellevue Mining Co., which is working a drift-gravel mine near La Porte.——Fifteen men are working at the Orient gravel mine.——Rich ore has been opened in the Sierra-Poorman mine.——The old Bald Mountain gravel mine is being reopened.

SISKIYOU COUNTY

The Southern Oregon and Northern California Mining Congress, I. J. Luce, of Etna, this county, presiding, which was held at Ashland, Oregon, during the second week in July, was rather lightly attended, according to the *Yreka Journal*. The display of minerals was not up to the standard, there being no exhibits from outside counties. The speakers who addressed the congress were able ones, which made the meeting interesting and instructive. Through the efforts of the persons from Siskiyou who attended, namely, M. J. Balfrey, editor of the *Etna Advance*; I. J. Luce and G. F. Hellmuth of Etna; G. M. Wells, manager of the *Farmer and Miner;* G. A. Reichman, of Fort Jones; and F. W. Armstrong, of Yreka, the next congress will be held at Etna Mills, Scott valley, during the month of June 1915. Scott valley is entitled to the congress as the valley and its tributaries have been great producers of gold and minerals; also, the people of Scott valley have always taken a great interest in the congress. F. W. Armstrong, of Yreka, gave an able address on the mineral resources of Siskiyou county; M. J. Balfrey, of Etna, addressed the congress on the advantages of holding the next convention in Scott valley. The following officers were elected for the ensuing year: president, James Logan, of Grants Pass, Oregon; vice-presidents, Mr. Metcalf of Kennett, O. A. Jillson of Shasta county, and G. A. Reichman of Fort Jones; secretary, G. F. Hellmuth, of Etna Mills; treasurer, J. W. Newman, of Redding, all of California.

COLORADO

GILPIN COUNTY

The Buckeye property, in the Quartz valley mining district, and owned by John Jenkins of Black Hawk, has been sold to capitalists of Grand Rapids, Michigan, through Thomas Cudahy, of Black Hawk, the consideration being $40,000. The new company will be known as the Gold Cup Mining Co. The claims have been opened to 200 ft., and show gold-silver-lead ore.——Operations are busy at the Gilpin Orion, Cyclops, Homer, Buckeye No. 1, Richardson, and other claims.

LAKE COUNTY (LEADVILLE)

The new zinc smelter is nearing completion, and the first lot of ore has arrived at the site. A number of contracts to supply ore have been made. Ores from Fryer Hill properties will supply the greatest tonnage for the start.——Recent developments in the Wolftone mine have been encouraging. Copper-gold ore has been opened in the Helen Gould claim in the East Tennessee district.——The Lake Park district is attracting considerable interest of late. The Silver Queen mine has been bonded by the Tulsa Mining & Milling Co. The ore contains gold and silver, also some copper and zinc. The mine has been idle for several years. Edward Best is manager.

SUMMIT COUNTY

The Breckenridge district is in a prosperous condition.——No. 1 dredge of the Tonopah Placers Co., four miles north of Breckenridge, made its first clean-up last week.——Gold worth $16,000 was sent from the Reiling dredge of the French Gulch Dredging Co. to the Denver mint.——Both of the Wellington Mine Co.'s mills are working full time. The ore-shoot at No. 5 level is opening well.

TELLER COUNTY (CRIPPLE CREEK)

On No. 11 level of the Elkton mine, on Raven hill, the Walter vein has been cut, showing 10 ft. of $30 ore, two streaks being worth $100 gold per ton.——The Portland com-

pany has distributed a 'safety first' pamphlet among its miners and millmen. This particularly draws attention to the evils of drink and subsequent accidents.——The Cresson Consolidated Gold Mining & Milling Co., a very close concern, held a meeting on July 15 for the purpose of considering the extension of the corporate existence of the Company, a mere formality. The main shaft on Raven hill is down 1500 ft., and the orebodies are said to be developing well. About $500,000 was paid in dividends last year. Richard Roelofs is superintendent.——In their contention that the county assessment of 1912 was invalid, the Vindicator and Granite companies have been upheld by Judge J. W. Sheafor of Colorado Springs. The county will appeal. If again upheld, the county would lose about $100,000 per year in taxes from the companies of the district.

RICO, DOLORES COUNTY, COLORADO.

IDAHO

Lemhi County

At the Musgrove mine, 35 miles west of Salmon, the mill and cyanide plant is working full time with good results. The Company has sufficient water power to operate the mill, and also an air-compressor for machine-drills in the mine. ——A 30-day mill-run by lessees at the Burlington mine, near Salmon, was satisfactory.——Stream tin has been found for some time in the placer workings of Eli Mineret in Prairie basin. He has had miners prospecting for the source of this mineral, and it is said that a lode has been found.——The Kirtley creek and Bohannon creek dredges, east of this place, are working this season.

Shoshone County

A shoot of copper ore cut in the Copper King mine at Mullan, last fall, is now being developed. It shows 5 ft. of 4 to 5% copper and 5 oz. silver per ton, opened for 127 ft. ——Some of the lessees operating in the upper workings of the Bunker Hill & Sullivan mine, at Kellogg, are seriously considering the advisability of erecting a concentrator near the mouth of the old Reid adit. Several have developed a large amount of milling ore, and the owners estimate that with a mill at hand it could be treated at a fair margin of profit. This would enable them to handle their shipping ore more advantageously and cut down considerably ore transportation charges.

MISSOURI

Jasper County

Good progress is being made generally in the Alba-Neck City district. L. G. Cole & Co. have let a contract for the erection of a 150-ton mill on the Penn Zinc Co.'s land at Neck City. The Shamrock Mining Co. will soon move its 150-ton mill to the Aylar ground at Alba. A mill will probably be erected by James Crissman & Co. between Alba and Neck City.

MONTANA

Silverbow County

The Butte-Duluth leaching plant produced about 127,000 lb. of copper in June. This is now treating 250 tons of ore per day. Leaching machines, electrolytic cells, and a 1250-hp. motor are to be installed for a total capacity of 1250 tons per day.

NEVADA

Clark County

Gold ore averaging $22 per ton has been opened in the Boss company's claims in the Yellow Pine district, 12 miles west of Goodsprings. Some rich ore has been selected and shipped to Utah.

Esmeralda County

Gravel from gulches around Palmetto, near the Nevada-California boundary, have yielded good results by panning and the dry process. The country around has been located for nine miles. The Nevada-California Power Co. has a substation at this point.——In a winze 85 ft. below the 100-ft. level of the Vernal mine at Goldfield, a vein 18 in. wide worth $250 per ton has been opened for 12 ft., according to the superintendent, Walter S. Norris.

Mineral County

At the end of last week there were 15 stamps working at the new Aurora mill. In June there were 220 men on the payroll. The Company will erect 30 cottages for employees near the mill.

NYE COUNTY

Owners of certain placer claims in Tule cañon have been bothered with water in the shaft, but a Ford automobile is now used to drive a pump. This is done by jacking up the rear axle, taking off the tires, and putting a belt on one wheel of the machine and the pump. Bedrock is at 35 ft. ——The Nevada Cinnabar Co., at Ione, is producing eight flasks of quicksilver per day. Fifty tons of 2½% ore is mined daily from a glory-hole. Two cords of wood is used per day in the furnaces. A 44-hp. gas-engine operates the plant.

Tonopah mines produced 11,617 tons of ore, worth $299,555, during the week ended July 18. June outputs were as follows: Belmont, 14,973 tons, 281,417 oz. silver bullion, and $120,859 profit; Tonopah Mining, 11,705 tons, 214,775 oz. bullion, and 94 tons of concentrate worth $29,470, and $80,540 profit; Extension, 4673 tons, yielding $68,651 and $19,090 profit; and Jim Butler, 4130 tons and $28,017 profit.——An adjustment of the Jim Butler-West End suit may be arranged by Charles E. Knox.

WHITE PINE COUNTY

Through granting the Wide West Mining Co., at Cherry Creek, permission to use the North Mountain Mining Co.'s 1200-ft. adit, the latter Company may reopen its property after an idleness of 15 years. When shut down it was 190 miles ffom a railway, and there was no improved cyanide process for ore treatment. Three shafts have been sunk 80, 300, and 600 ft., and the adit driven 1200 ft. Some large shoots of $7.50 to $15 gold ore were opened. One lot of 2100 tons from the main shaft averaged $10 per ton. There is a good deal of equipment on the ground.

UTAH

JUAB COUNTY

A report covering the term April 30 to December 31, 1913, has recently been issued by the Silver King Coalition Mines Co. The cost of excavating, concreting the station at the new Silver Hill shaft, which is 1670 ft. under the surface and 8400 ft. in from the mouth of the tunnel, was $46,770. The cost of compressors, electrical appliances, etc., was $50,422. Driving is under way on the 100-ft. level of this shaft, or 1770 ft. deep. The shaft is to be sunk to the orebodies on the lime-quartzite contact, 1000 to 1200 ft. below the collar, or 2700 to 2900 ft. deep. The profit during the period was $363,390, of which $182,970 was paid in dividends. With the previous balance there was a surplus of $904,466, but the Silver King Consolidated suit damages were $896,822 net, leaving a balance of $7644.

Some good silver-gold-copper ore, with some lead, has been opened in the Dragon Consolidated northern part of the property, where it is being developed from the 600-ft. level of the Iron Blossom. Water from the 800-ft. level of the Dragon is being used at the Knight-Christensen mill.——The Eagle & Blue Bell company has paid a dividend of 5c. per share, equal to $44,657.

WASHINGTON

FERRY COUNTY

A franchise, not exclusive, to erect and maintain power-transmission lines on all roads in this county has been granted to Mahlon McCain and Fred M. Shields of Spokane. A 33,000-volt line to cost $30,000 is to be erected within six months. At Danville, 30 miles from Republic, the line will connect with that from Bonnington Falls, British Columbia, owned by the West Kootenai Power & Light Co., which will generate the power for the Republic district.

CANADA

ONTARIO

The Hollinger mill treated 13,928 tons of $14.59 ore in June. The recovery was 95.2%; all costs, $4.58 per ton; and total profit $129,168. The srplus is $859,225. Dividends now total $2,000,000.

The Dome output in June was 18,250 tons of ore averaging $4.51 per ton.

Dividends paid by Cobalt and Porcupine mines to date amount to $53,638,011 and $2,100,000, respectively. Disbursements for the current year are as follows:

Name.	1914.	To date.	Return on capital, %.
Coniagas	$ 720,000	$ 6,640,000	176
Temiskaming & Hudson Bay	69,849	1,940,250	25.000
Caribou Cobalt	50,000	75,000	7½
Crown Reserve	247,634	5,784,082	327
Kerr Lake	300.000	5.220,000	174
La Rose	524,525	4,600,346	64
McKinley-Darragh	404,585	4,269,597	72
Nipissing	1,050,000	11.940,000	199
Trethewey	50,000	1.061,998	108
Seneca Superior	179,581	490,356	102½
Casey Cobalt	93,750	203,249	15
Buffalo	280,000	2,787,000	282
Cobalt Lake	150,000	465,000	15½
Cobalt Townsite	199,953	966,726	97½
Hollinger	540,000	1,980,000	66
Porcupine Crown	120,000	120,000	6
Total	$5.039,877	$48.544,604	.....

At the Tough Oakes mine, 27 tons of 32.25 oz. gold ore has been bagged. A report on the property by H. H. Johanson states that there is 26,000 tons of ore blocked out, 22,000 partly developed, and 8000 tons per month should be added to the reserves by development.

CHILE

Owing to storms and snowslides affecting transportation and the cutting off of electric power, the production of the Braden mine showed a decrease during June. There was milled 42,000 tons of ore averaging 2.2% copper, producing 3300 tons of 17% concentrate, the recovery being 63.35%. Production totaled 662,000 lb. The Company met its fixed charges during the first half of the year with a small surplus. Production totaled 12,845,000 lb. during the year, comparing with 8,438,-000 lb. last year and 3,398,000 lb. two years ago. The following shows results at Braden in the first half of 1914:

Month.	Tons.	Copper, %.	Extraction, %.	Production, lb.
January	98,020	2.15	72.70	2,426,000
February	79,296	2.08	68.63	2,362,000
March	83,900	2.19	72.18	1,801,000
April	83,900	2.35	69.90	2,720,000
May	70,477	2.11	75.36	2,480,000
June	42,000	2.20	63.35	662,000

KOREA

The Oriental Consolidated Mining Co.'s output in April was $127,900.

MEXICO

SONORA

Colonel Calles, in charge of the forces at Cananea, has threatened to execute or deport all labor agitators, which brought the men to their senses. Eighteen were deported on July 14. Furnaces of the Greene Cananea company are again being blown in, and a full resumption of work is expected.

PHILIPPINE ISLANDS

A total of 1328 oz. gold was recovered from the Philippine Dredges, Limited, three boats in May. No. 1 treated 30,750 cu. yd. for 374 oz.; No. 2, 37,000 cu. yd. for 444 oz.; and No. 3, 60,000 cu. yd. for 510 ounces.

PERSONAL

H. F. Juhs is in San Francisco.

C. R. Forbes is visiting California.

D. C. Bard is examining mines in northern Montana.

R. A. F. Penrose, Jr., was in San Francisco Wednesday.

B. B. Thayer is on his semi-annual inspection trip to Butte.

Stephen L. Goodale is spending the summer at Saco, Maine.

W. H. Storms is in Plumas county on professional business.

Henry H. Armstead sailed from New York for Mexico on July 10.

Hennen Jennings is in San Francisco and will stay for some weeks.

R. H. Sales has been examining copper properties near Ketchikan, Alaska.

Ralph Arnold has returned from the East and was in San Francisco this week.

Howland Bancroft was married July 15 to Miss Alice Hannon at Dorchester, Massachusetts.

E. J. Carlyle, formerly of the Washoe smelter, has accepted the management of a copper smelter near Perm, Russia.

W. Lorrain Cook, formerly of Mexico City, is now superintendent of the Cia. Huanchaca de Bolivia, at Placayo, Bolivia.

R. H. Hutchison has resigned from the Coniagas mine, Cobalt, to go to the mining branch at the High School at Sudbury.

J. S. Diller, government geologist, has returned to Redding to make another and more detailed examination of the volcano at Mt. Lassen.

Walter W. Bradley, of the California State Mining Bureau, is investigating the mineral resources of Fresno, Merced, and other central counties of the state.

H. N. Thomson, formerly of Anaconda and Tooele, is at Clarkdale, Arizona, as consulting metallurgist at the new plant of the United Verde Copper Company.

F. A. Glynn, master mechanic for the Nevada Con. Copper Co. at Copper Flat, has resigned to accept the position of master mechanic for the Chile Copper Co. at Chuquicamata, Chile.

C. M. Eye has been appointed manager for the Benguet Consolidated at Bagui, Philippine Islands, and will sail on the *Minnesota* September 26. In the meantime he has gone to Colorado to test a shipment of Benguet ore and to purchase machinery for the mine.

Silver Market Conditions

The tone of the silver market is fairly steady, though dull, according to Samuel Montagu & Co. of London, writing on July 9. A certain amount of selling on account of China during the earlier part of the week, in addition to the ordinary supplies, rather overweighted the market, and prices eased for both deliveries on July 6. The pressure to sell from China then ceased, and a preference to buy for forward delivery at the slightly reduced level carried the quotation for two months to a premium of 0.12c. Inquiry has been fairly good from the Indian bazaars, and purchases have been made for the Continent. An examination of the statistical position of the exports and imports of silver for the first six months of this year afford little justification for the present lifeless condition of the market. The total imports for the last six months were 47,297,160 oz. as against 62,457,666 oz. in the similar months of 1913. The total exports this year up to the end of June were 10,854,795 oz. in excess of the total imports, so that the stock in London had to be heavily reduced in order to fill the demand. As a matter of fact, the visible stock in London shrank from 15,800,000 to 4,400,000 oz. during the period named.

SOCIETY MEETINGS

AUGUST

American Institute of Mining Engineers, Salt Lake City	10-14
British Association, Adelaide, South Australia	8
Canadian Mining Institute, Rocky Mountain branch, Banff.	
Lake Superior Mining Institute, Ishpeming, Michigan	31 to Sept. 3

SEPTEMBER

American Chemical Society, Montreal	15-18
American Institute of Electrical Engineers	not fixed
Colorado Scientific Society, Denver	3
Illuminating Engineering Society, Cleveland	21-25

OCTOBER

American Institute of Electrical Engineers	9
American Iron and Steel Institute	23-24
Colorado Scientific Society, Denver	3

NOVEMBER

American Institute of Electrical Engineers	13
Colorado Scientific Society, Denver	7

DECEMBER

American Institute of Electrical Engineers	11
American Museum of Safety	11-20
American Society of Mechanical Engineers	7-8

SCHOOLS AND SOCIETIES

The French Government has authorized construction of new buildings for the National School of Mines at St. Etienne, estimated to cost about $308,224.

The Panama section of the American Institute of Electrical Engineers held a meeting in the control house at Pedro Miguel lock on July 12. R. H. Whitehead presented a paper entitled 'Hydraulics of the Locks.' The rates of filling the lock chambers and the currents during lockage were discussed. Various features of the paper were demonstrated by actual operation of certain of the valves and gates.

The American Association for the Advancement of Science, the largest scientific organization in the United States, has decided to hold a general meeting of the Association in San Francisco and vicinity on the occasion of the Panama-Pacific Exposition in 1915. A committee of 31 representative scientists of the Pacific coast has been appointed to make the necessary arrangements. W. W. Campbell, astronomer and director of the Lick Observatory on Mount Hamilton, is the chairman of this committee; and John Casper Branner, president of Stanford University, is chairman of the general committee on scientific program. The Pacific Coast committee has recommended, and the American Association has approved, that the sessions of the meeting shall begin on Monday, August 2, and terminate on Saturday, August 7. It has also been decided that the general sessions of the meeting shall be held in San Francisco together with the general evening lectures open to the public, and through the courtesy of Stanford University and the University of California, that sessions for the presentation of addresses and papers in the separate divisions of science will be held in the halls of these universities. Subcommittees of the Pacific Coast committee have been appointed to supply information to the members of the American Association and to the members of such other societies as may desire it, on transportation by railways and by steamers.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 23.—Copper is weak here. In London the Amalgamated and Phelps-Dodge agencies quote 13.60c. for electrolytic; Hirsch, 13.75c.; and A. S. & R., 13.90c. Nevada Consolidated output in June was 1,483,175 lb., and Ray Consolidated, 6,226,536. Lead and spelter are unchanged, the latter being firmer in New York. In St. Louis lead is firm at 3.75c., and spelter strong and higher at 4.90c. Tin is firm at 31.62 to 31.87c. Bar silver in London is steady at 24⅝d. (50¼ cents).

SILVER

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask

or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Gold imports and exports into London during the first half of the past three years are as follows:

	1912.	1913.	1914.
Imports	£24,810,548	£25,476,141	£28,934,112
Exports	19,533,236	18,841,946	22,364,842
Net imports	5,277,312	6,634,195	6,569,270

The Westinghouse strike at East Pittsburgh has been called off by the workmen on Thursday, July 9. While the date set for return to work was Monday, July 13, a large number of the men reported on the Friday and Saturday preceding. All the strikers were taken back with the exception of 300 men. The works are now running full time.

Camp Bird and Santa Gertrudis Affairs

On account of the Grenfell failure in London, several weeks ago, H. C. Hoover was appointed temporary chairman of directors of the above Companies on June 17. On the 25th he explained the situation to a number of English and French shareholders, who asked him to continue as chairman. J. S. P. Samborne resigned his position as a director of the Companies, and there is nothing reflecting on him, as he was abroad when the outstanding loans were made. But as he was a director of the Canadian Agency, Mr. Samborne felt that he should resign. R. J. Frecheville also resigned. He was for many years a technical member of the board, and consulting engineer, confining himself to the technical operations of the Companies and leaving the financial business of the Companies in the hands of the late chairman, A. M. Grenfell, whose assurances as to its administration there was no reason to question. Mr. Frecheville felt that as it is the desire of a large body of shareholders that there should be additions to the board, and that as his activities on behalf of the Companies are of a technical order, he would prefer to become the chairman of the technical committee which it is proposed to set up for the conduct and technical adminstration of the Companies' mines. Mr. Hoover was sure that the continuation of Mr. Frecheville's association would be of the greatest advantage to the Companies, and he had no hesitation in engaging his continued services as above. F. W. Baker was an active director and remains on the board. F. A. Govett of the Ivanhoe Gold Corporation, F. H. Hamilton of the Spassky Copper Co., and George de Pass, a large shareholder, have also joined the board of the Camp Bird; and the first two with Norman Craig joined the Santa Gertrudis board. The annual meetings will be held in September next.

Before accepting any responsibilities, Mr. Hoover insisted upon a special audit of the London accounts by Price, Waterhouse & Co. This shows the following condition of finances: Camp Bird assets: Santa Gertrudis shares, £1,122,328; Messina (Transvaal) Development shares, £4483; Nechi Mines (Colombia) shares, £790; Anglo Colonial Estates shares, £2500; and Imogene Basin company shares, £1000. In connection with a property in Central America, £40,095 was spent, and the Camp Bird has £36,500 7% income notes and 89 £1 shares in the controlling syndicate, the Central American Goldfields Syndicate, Ltd. Loans against security total £41,875; cash balance at Lloyds Bank, £23,856; and Glyn, Mills, Currie & Co., £5006; other balances, including Chaplin, Milne, Grenfell & Co., £15,871; and Canadian Agency, £795, against security of 3000 shares in Algoma Eastern Railway Co., 12,000 shares in Alberta Land Co., and 475 shares in Emba Caspian Oil Co. Liabilities include dividend on preference shares to June 30, 1914, £22,750; directors, office, taxes, etc., £2493; unclaimed dividends, £3508; and further contingent liabilities in the Nechi Mines, Anglo Colonial, and Central American Goldfields Syndicate, totaling £3770. The general manager at the Camp Bird mine, William J. Cox, estimates a profit of £60,000 remaining in the mine.

Santa Gertrudis assets: Compania de Santa Gertrudis and Compania Beneficiadora de Pachuca, shares, £252,101; Amistad y Concordia Aviado and Recuperadora, shares, £93,763; Messina (Transvaal) Development Co., £28,125; loans against security, £50,980; cash at Lloyds Bank, £64,611; and Glyn, Mills, Currie, & Co., £30,000; Chaplin, Milne, Grenfell & Co., £11,177. Liabilities include commissioners of inland revenue, £16,000; and directors, office, etc., £1165. Owing to trouble in Mexico, the mill is not working, but the mine is being developed without interruption.

Mr. Hoover estimates that the total loss which the Santa Gertrudis need incur on account of the loans against the Companies that failed need not exceed £27,000.

COMPANY REPORTS

CROWN MINES, LIMITED

Discussion of this great Rand company's results in 1913 will be found in the 'Review of Mining' of this issue. The following data are from the report for the past year:

	1912.	1913.
Ore reserves, tons	10,607,671	10,449,000
Stamps working (835 erected)	.....	660
Tube-mills working	.....	24
Ore treated, tons	2,183,305	2,483,622
Gold produced	£3,071,217	£3,248,132
Working profit	1,314,247	1,442,473
Cost per ton	.....	$3.94
Dividends	1,034,116	1,034,116

GREAT FINGALL CONSOLIDATED, LIMITED

This is a Western Australian company operating an interesting mine and mill at Day Dawn, about 150 miles northwest of Kalgoorlie. Production to March, 1914, was 1,858,885 tons yielding gold worth £4,633,650, and dividends amounting to £1,749,875. The output in 1913 was 64,255 tons averaging $6.06 per ton. The following notes are from the report of the general managers, Bewick, Moreing & Co., the superintendent being C. H. Nicholson:

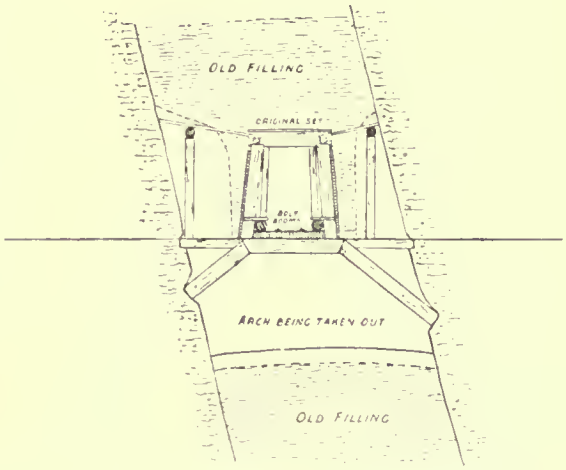
Development totaled 1921 ft., also 583 ft. of timbering and 5580 cu. ft. of excavation on the internal shaft. Driving, cross-cutting, raising, sinking by winzes, and work on the internal shaft cost $31.05, $30.21, $35.28, $45.44, and $178.87 per foot respectively. Interest centred around work at the internal shaft, which starts at No. 13 level, a vertical depth of 1519 ft., and is now below No. 18 level, which is 2280 ft. On No. 16 level the orebody was opened north for 194 ft., averaging $8.64 over 52 in. Winzes below No. 18 show good ore. Ore reserves, below No. 14, are estimated as 69,442 tons worth $9.20 per ton. Above No. 14 the available ore is negligible, although last year six levels above this one produced 41,712 tons. Forty stamps worked 64.27% of the total time, and averaged 7.05 tons of ore per 24 hours each. The cyanide plant residue averaged 27c. per ton, and the recovery was 91.49% at a cost of $2.13 per ton.

The year's income was £124,221, and operating expenses £96,964. After paying for purchased ore and concentrate, and special development, there was a deficit of £12,550 in Western Australia. On adding the previous balance, there was a surplus of £15,308, of which £12,500 was paid in dividends.

WAIHI GOLD MINING COMPANY, LTD.

The report of this great New Zealand company for 1913 is a voluminous publication of 80 pages, with an index, and contains all information necessary from the respective officials, E. G. Banks, superintendent; W. P. Gauvain, assistant superintendent; J. L. Gilmour, mine manager; and S. E. Fraser, engineer at the Victoria 200-stamp mill and cyanide plant. The output of gold and silver since 1890 amounts to £10,454,869, of which £1,478,539 was paid in dividends, and £386,769 as income tax.

In the mine, down to and including the No. 11 level, a total of 13,466 ft. of development was performed. Three shafts were sunk a total of 141 ft., these being 1227, 1256, and 1319 ft. deep respectively. Various work was done in the shafts in connection with the pumps. The 'C' Hathorn-Davey pump lifted 375,760,648 gal., and the electrically driven pumps 161,574,495 gal. of water during the year. Two air-compressors, each with 1750 cu. ft. capacity, were in use; one is steam and the other gas driven. The twenty-four 3¼-in. machine-drills, and eighteen stoping hammer-drills at work. Approximately 121,135 tons of waste was run into stopes. Development cost 59c. per ton milled. An important development in 1913 was the cutting of a profitable lode between the Empire and Royal lodes, and known as the Dreadnaught, 88 ft. below No. 10 level at No. 4 shaft. It has since been opened on No. 8, 9, 10, and 11 levels, there being 730 ft. of profitable ore on No. 10, 2 to 5 ft. wide and 160 ft. on No. 11. A branch vein on No. 10 has been driven on east for 231 ft., showing up to 4½ ft. of fair ore. Development on the Martha lode was disappointing on No. 10. On this level the Edward lode was 75



METHOD OF REMOVING ARCHES FROM STOPES 15 TO 20 FT. WIDE.

ft. wide in the first cross-cut, and profitable, but in other cross-cuts the lode is not so good. Ore reserves total 764,732 tons, not including 23,271 tons in dumps at the mine. Broken ore in shrinkage stopes on five lodes amounts to 42,934 tons, of which 41,202 tons is on the Royal lode. Ten lodes supplied the Victoria mill, 6 miles from the mine, with 184,768 tons of ore. Financial results were as follows:

Gold and silver revenue	£336,652
Interest	15,487
Balance from 1912	17,957
Total income	£370,096
Expenditure in New Zealand and London	211,395
Dividends (4)	99,181
Income tax (New Zealand £3504, and London £18,984)	22,488
Depreciation, money for Hora Hora electric account, etc.	27,837
Balance for 1914	9,194

Reserve account stands at £90,000, and investments at cost, £379,283. Stores are worth £28,933.

During the current year the Hora Hora hydro-electric scheme, 50 miles distant from the mine, on the Warkato river, was completed, and at the end of April 1914, 1100 hp. was being used at the mill, and 650 hp. at the mine. More motors are being brought into commission as they are ready. Great difficulties were experienced in erecting steel towers and transmission lines over the rough Te Aroha ranges of 2500-ft. altitude. A separate account is kept of this scheme, and the balance-sheet to December 31, 1913, shows that the Company provided £186,490 from revenue, reserve, and New Zealand government debentures. This amount, except £469, was spent the land costing £716; generating and construction plant, £102,289; transmission, £65,064; roads and bridges, £1927; and general expenses, etc., £17,741. Metallurgical work will be discussed in another issue of the *Press*.

MINING DECISIONS

Mineral Lease—Defects Cured

Failure of the lessee under a mineral lease to pay rentals, pending commencement of work thereunder, is satisfied by his subsequent commencement of work at the instance and request of the lessor or the lessor's successors in interest, and the lease cannot thereafter be declared forfeited for such non-paymnt.

Hudspeth *v.* Producer's Oil Co. (Louisiana), 64 Southern, 891. March 30, 1914.

Invalid Location—May Not Be Usurped in Bad Faith

Where the facts showed that one locator was in actual possession and occupancy of property after the discovery by it of oil thereon, the entry of other locators in bad faith and without any right or color of title, and subsequent ouster of the first locators does not entitle the junior claimants to make a valid location on the ground even though it be shown that the prior location was invalid. Under such circumstances the first locator could maintain ejectment against the second.

Little Sespe Consolidated Oil Co. *v.* Bacigalupi (California), 139 Pacific, 802. March 2, 1914.

Mining Company May Become a Public Utility

A mining company maintaining an electric power-plant for its own use, but supplying electricity for lighting purposes to such inhabitants of an adjoining village as have applied for service, is a public-service corporation within the meaning of the public utilities act, and can be compelled by the public service commission to furnish service to the complainants who were residents of the village, even though the corporation's charter contained no authorization to sell electric power. The corporation cannot plead ultra vires as to one consumer and continue to furnish service to others.

Wingrove *v.* Public Service Commission (West Virginia), 81 Southeastern, 734. April 21, 1914.

Ownership of Natural Gas—Character of Title

Where an owner of a tract of land executed a gas lease thereto upon stipulated royalties, and thereafter conveyed a portion of the tract to another, the grantee acquired the right to royalties from wells bored on the conveyed portion but not from wells drilled on the portion retained, even though it was proved that such wells drew the gas from beneath the conveyed portion. The ownership of gas beneath a tract of land is only a qualified title in the land-owner, conditioned upon his reducing the same to actual possession. Hence the grantee could not recover any part of the royalties received by his grantor from wells drilled on the grantor's land.

Fairbanks *v.* Warrum (Indiana), 104 Northeastern, 983. April 24, 1914.

Oil Lease—Implied Covenant for Diligence

A lease granted 'all the oil and gas' under the leased land together with the right to enter 'at all times' for the purpose of 'drilling and operating,' to erect and maintain structures, pipe-lines, and machinery necessary for the production and transportation of oil and gas, reserving royalties to the lessor, and providing that drilling must commence within ninety days from the date of said lease. Held, that as the lease did not expressly define the measure of diligence to be exercised in the work of development, that the implied obligation would be construed to require development work along such line as will be reasonably calculated to make the extraction of oil and gas from the leased land of material advantage and profit to the lessor and lessee. The right to forfeiture for breach of this implied covenant, however, must be exercised with reasonable promptness. Continued acquiescence in the lessee's plan and measure of development and payment of royalties will bar the lessor's right to a forfeiture.

BOOK REVIEWS

Engineering Geology. By Heinrich Ries and Thomas L. Watson. P. 667. Ill., Index. John Wiley & Sons, Inc., New York, 1914. For sale by the *Mining and Scientific Press.* Price $4.00.

It is no easy task to write a geology for engineers, for the reason that, essentially, geology is a science and engineering is an art. The skilled geologist is one trained long in the methods of scientific investigation; the engineer is one who accepts facts as they are, or even, often, as they appear to be, and makes the most of it. Many engineering structures have failed and all too many mistakes have been made because the engineer responsible had a too limited knowledge of geology. If, however, he had taken the years necessary to become a skilled geologist, he would probably not have become an engineer; and certainly geologists, speaking as one of them, can claim to no inborn skill that would entitle them to consider themselves as engineers. The chasm is not to be bridged save by a very few exceptional individuals who absorb knowledge apparently without effort and can think geologically while they build with the hard practical sense of the engineer. The ordinary busy practitioner will do quite well enough if he fortify himself with a sense of when it is necessary to call on the geologist for advice. The behavior of rivers, the vagaries of underground waters, the puzzling irregularities in the weathering of stones, and the unexpected effects on foundations of these and other geologic factors, are not to be learned by the engineer as an incident to his schooling. What is inexcusable for him is not to know when there is danger to his work from such a source. He must be on his guard and must be ready to call for assistance in planning his work.

The authors of the text-book under review have recognized this fact, and have not attempted the impossible, the making of geologists out of engineering students. Their book is frankly informational, and only the simpler methods of geologic field work are explained and illustrated. Engineers, however, and especially civil engineers, will find the book fully worth not only the purchase price, but the time necessary to read it. It is thoroughly modern, and is authoritative. A wide range of subjects is treated, from landslides to ore deposits, and each is well treated. There is no other book that covers this field, and it is fortunate that the first one in it is so excellent in choice of subject-matter, form of presentation, and in printing and binding. H. F. B.

The Tractive Resistance of a 28-Ton Electric Car. By Harold H. Dunn. Bulletin 74, Eng. Ex. Station, Univ. Illinois.

This records the results of tests made to determine the attractive resistance of a 28-ton electric car when running on straight track in still air. The tests were planned so as to eliminate wind resistance. The results are finally expressed in the form of a curve whose coördinates are car resistance and speed, which shows that the resistance varied between 5.25 pounds per ton at 5 miles per hour, and 26.12 pounds per ton at 45 miles per hour. The bulletin contains also a description of the car.

RECENT PATENTS

1,097,672—Method of making white lead. Alexander S. Ramage, Buffalo, New York, assignor to The Chemical Development Co., Buffalo, New York, a corporation of Colorado.

The method of preparing basic carbonate of lead from lead sulphate, which consists in reacting upon lead sulphate with an alkali carbonate in less proportion than is required for the conversion of all of the sulphate into carbonate, and treating the resulting product with an alkali hydroxide.

1,097,156—Process of reducing ores. Harvey Carroll Alford, St. Louis, Missouri.

In the reduction of metallic oxides, the process of externally heating a charge of the crushed material within a suitable container to a temperature approximately 1000°F., then mixing therewith, without access of air, a hydrocarbon with an excess of carbon sufficient to prevent reoxidization of the metal of the reduced oxide externally heating the mixture, thereby extracting the metal in the presence of such carbon excess.

1,097,227—Electrode for electric furnaces. Arthur Thacher Hinckley, Niagara Falls, New York.

An electrode for electric furnace uses, having at one end an integral pin of less diameter than the electrode, which pin has an annular groove, and having at its other end a longitudinal hole which is similar in shape and size to said pin, said hole having in its longitudinal wall an annular groove, and there being a lateral hole leading from the outer surface of said electrode to the grooved part of said longitudinal hole.

1,101,115—Extraction of copper and nickel, particularly from low-grade ores and products. Wilhelm Borchers, Aachen, Germany, and Harald Pedersen, Trondhjem, Norway.

Smelting the ore to a matte, roasting the matte, leaching the roasted material with acidulated water, precipitating from the resulting sulphate solution the copper by means of hydrogen sulphide, converting the precipitate into metallic copper, evaporating the residual nickel sulphate solution, roasting the dried nickel sulphate to convert the same into nickel oxide, and finally reducing the same to metallic nickel.

1,101,506—Process for the separation of metallic sulphides from gangue and apparatus therefor. Leslie Bradford, Broken Hill, New South Wales, Australia, assignor by mesne assignments to Minerals Separation, Ltd., London, England.

A process of concentrating ores which consists in mixing the ore with water to form a flowing pulp, adding to the pulp sufficient acid to bring about the evolution of gas by chemical action of the acid, subjecting the pulp and evolved gas therein to violent agitation, and then flowing the agitated pulp away from the place of agitation and separating the floating material.

1,100,671—Rock-drill. Louis W. Greve, Cleveland, Ohio, assignor by mesne assignments to The Cleveland Rock Drill Co., Cleveland, Ohio, a corporation of Ohio.

A hammer piston, a rotatable chuck, a drill steel extending through the chuck in slidable but non-rotatable engagement therewith, a piston working transversely with the chuck, a pawl provided with a plurality of ratchet teeth and mounted for oscillatory movement above the chuck and having engagement with the last-mentioned piston, a ratchet wheel encircling the chuck in slidable but non-rotatable engagement therewith, and a spring pressing the ratchet wheel longitudinally of the chuck so that its teeth engage the teeth of the pawl.

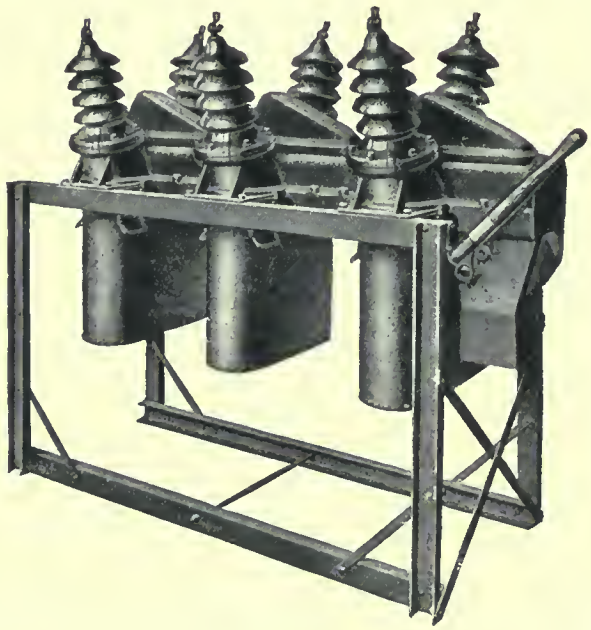
New Machines and Devices

New High-Voltage Oil Switch

The general principles of operation of indoor and outdoor oil switches are the same, but some of the details of construction are obviously different. In addition to performing the usual duties, the outdoor switch must be so constructed that successful service will result while exposed to the effects of the severest weather. All moving and operating parts must be totally enclosed and fully protected.

The new type F, form K-22 oil switches manufactured by the General Electric Co., Schenectady, New York, are designed for this purpose. They are built in single-pole elements and are



HIGH-VOLTAGE OIL SWITCH.

operated by hand, solenoid, or air. The mechanism for each element is self-contained and mounted on the top of a steel tank.

The standard hand-operating level consists of a removable wooden handle attached directly to the switch mechanism. This handle is removable to guard against unauthorized operation. The solenoid mechanism is similar to the hand mechanism, except that a direct current solenoid with a rod for connecting to the mechanism is used instead of the operating handle.

Since the insulating properties of oil are superior to those of air, the bushings are inserted through the cover at an angle converging at the lower end, which reduces the size of the oil tank necessary for any given voltage. The contacts are of the well known 'sliding-wedge' construction. Each phase contains two contacts in series. The stationary ones consist of widely flared fingers and extra long arcing tips of drop-forged copper. The movable element of the contact is a wedge-shaped copper blade. This blade moves in a vertical plane, being drawn up by the switch mechanism when the switch is closed and dropped by gravity assisted by springs when the switch opens. The switches are as a rule tripped on overload by trip coils acting directly on the switch toggle and operated by bushing-type current transformers; although the other methods of tripping oil switches in general use can be applied. The bushing transformer has been designed to furnish at a low cost a series transformer for high-tension systems. It may also be used to furnish current for ammeters where approximate accuracy only is required.

Commercial Paragraphs

Fred M. Prescott Steam Pump Co., of Milwaukee, Wisconsin, has for distribution Bulletins P-105 and P-106, which are devoted to power pumps for mines. All gears used on the power pumps are of cut double helical or herring-bone type and the many types of pumps presented are adapted to the varying conditions found in the operation of mines.

Marion Steam Shovel Co., Marion, Ohio, has recently published an attractive booklet entitled 'Stripping Coal with Economy and Speed.' Under the title, 'When Nature Meets You Over Half Way,' there is presented a brief history of the coal mining industry which is replete with illustrations showing the many applications of Marion shovels to coal mining.

The Redwood Manufacturers Co., San Francisco, has been awarded the contract by the Anaconda Copper Mining Co., of Butte, Montana, for the construction of 15 redwood slime-treatment tanks, which are 50 ft. diameter and have 14-ft. staves. The tanks are to be erected at the Anaconda plant of this Company.

The W. S. Tyler Co., of Cleveland, Ohio, has just recently issued catalog No. 36 which is descriptive of the testing sieves manufactured by this Company. The Tyler standard testing sieves are made from 6 to 12 in. diameter and from 1 in. opening to 300-mesh. For laboratory use the 8-in. sieve with brass frame is recommended. The 6, 7, and 8-in. sieves are made with dies that produce a seamless metal rim across which the cloth is stretched lightly. Sieves of this size are also furnished with bottom pan and cover which are pressed from sheet metal and made to fit each sieve of the set. The use of a pan and cover is to be advised as they facilitate the sifting operation and protect the fine wire cloth from injury when not in use. Telescope nests of sieves are also made by this Company. The bulletin also contains suggestions for testing together with considerable data on the use of screens in analytical work.

The Chain Belt Co., Milwaukee, Wis., has recently issued catalog No. 54 which is descriptive of the 'Chabelco' steel chain belt manufactured by this Company. The chain belt is an all steel, case-hardened-bearing roller chain belt. The side bars are punched from mild steel bar stock and the rollers for transmission purposes are made of the best grade of cold rolled steel shafting, which are machined out of the solid on automatic turret lathes. The object has been to obtain a metal having the correct hardness without brittleness and strength without softness. The rollers for elevating and conveying purposes are made of cold rolled steel, cast steel, or gray iron and the bushings are stamped out of cold rolled pickled steel. The pins are made of forged steel and milled flat on the ends to fit oblong holes in the side bar to prevent turning. The catalog contains a large amount of information regarding the different products of this Company together with illustrations of different installations of the 'Chabelco' steel chain belt.

THE unhesitating and non-mediatorial manner in which Austria and Servia have set about adjusting their trivial differences will no doubt bring forth the plaudits of the jingo element of this country, which is still lamenting the fact that the United States is not at war with someone.

JAPANESE spelter is now offered at Liverpool, which is evidence of the growth of the Japanese zinc industry during the past few years. Until recently Japan has imported zinc, but the zinc production has increased to 600 tons per month, which is double the consumption of the country and has made it necessary to seek a European market.

COMPLAINT is made by subscribers and others at Dedrick, California, of non-delivery of mail owing to expiration of the contract for transportation from Junction City and failure of the contractor to agree with Postoffice officials on new rates. This is one of the incidental results of the introduction of parcel post. The matter has been taken up with the authorities for adjustment, but in the meantime letters addressed to Junction City will probably reach the persons to whom they are addressed.

SEEING ourselves as others see us often produces a shock. An English friend sends without comment a story of an American found wandering through the Geological Museum on Jermyn street, London. After inquiring as to the price of real estate in the neighborhood he is quoted as saying: "They try to make out that England is a back number, but when I get up against a country that wastes real estate worth hundreds of thousands on a place where no one ever comes, I've no more to say. It's too big a proposition for me."

THE provisional Government of Peru has recently issued a decree confirming the resolutions of 1910 and 1913 which prohibit the denouncement of petroleum producing land in that country. The object of the decree has been to prevent the location of other mineral claims on territory, which is in reality petroleum bearing, for the purpose of obtaining control of the oilfields. Under the Peruvian mining law, while an individual may denounce a claim for specific mineral, he is privileged to exploit the ground for any other mineral which it may contain.

CONFERENCES of diamond producers held in London recently are reported to have resulted in a curtailment in output. While no details have been made public, it seems to be generally understood that an agreement has also been reached between the South African interests and the German producers. The decline of the American market during the past year is held to be largely responsible for the present agreement. Shipments from South Africa last year were almost equal to the record production of 1910 and the price per carat shows a material advance; it is therefore difficult to see the logic of curtailment and is evidently only proposed to meet a temporary flurry in the market.

POLITICIANS may have gained, but the country lost heavily when Mr. Thomas D. Jones failed of confirmation by the Senate for a position on the Reserve Board. As one of the famous family that made the Mineral Point Zinc Company, Mr. Jones is well known to mining men, and to those intimate with the commercial life of Chicago and the Middle West in almost any phase, his name, if not his tall spare figure, is equally familiar. He is a man who looks at business in a large way and that he would have made a fearless and upright public official was assured by the career of his brother, who gave an excellent administration of the Indian office at the time that such administration was worse needed and less common than now, as well as by his own business record.

GROWTH of rumor is well shown in the newspaper reports that a second and more serious strike will soon be on in the Lake Superior copper district. A labor agitator, with no knowledge of actual facts, made some silly remarks at a convention; these were repeated and modified by others until they took the form of a definite statement that a general strike is imminent. As a matter of actual fact the district is remarkably free from unrest and is full of men seeking work. Nearly all the mining companies are increasing the scale of their operations as rapidly as possible, in order to decrease cost by increasing output, but with this it is impossible for them to take on all the men who are coming in from the iron ranges where production is at an unusually low ebb. If the leaders of labor agitation really are planning to attempt to incite a new strike in the 'copper country' they could scarcely choose a more inauspicious moment than the present.

THE Department of Agriculture is excepted in the recent action of Congress which prohibits government bureaus from sending representatives to meetings of the various associations and societies at public expense. In the past the Government has rightfully encouraged the coöperation of the bureaus with representative societies, and great good has been accomplished among others by the Bureau of Mines, through the friendly relations thus fostered. Of course the farmers have a great many votes, but why should this discriminate against the mines department? If a bureau is to collect and disseminate information, why not permit it to do this in the most effective way?

PLANS for the model mine at the Panama Pacific exposition are coming forward nicely. The coöperation of a number of the leading mining companies and machinery manufacturers is going to make possible a really educational exhibit. The effort will be to reproduce as closely as space will permit, actual stopes from representative mines. The list now assured includes the Bunker Hill & Sullivan, Goldfield Consolidated, Homestake, Copper Queen, a Jones & Laughlin iron mine stope, and rooms showing coal mining in both anthracite and bituminous fields constructed by several of the leading companies. Others are tentatively promised. Bureau of Mines officials who are in charge of the enterprise are meeting with every encouragement and we believe the mine will be one of the most instructive exhibits at the Exposition. If it serves the purpose of giving the general public a real insight into mining, a 'perceptive centre' around which to build an accurate concept of underground conditions, it will be well worth the time and labor expended.

THE personnel of the Foreign Trade Council, which has been created by a resolution presented at the national foreign trade convention, is most representative of American business, and if this council is to be a live organization, the purpose for which it was created could not be better represented. Mr. James A. Farrell, president of the United States Steel Corporation and chairman of the council, in outlining the purpose of this body, states that it is a necessary preparation for the evolution and expansion in the business life of the country. By gathering active and representative business men into such a body and coöperating with all firms in our oversea commerce, it is hoped to encourage every practical and sound policy designed to secure for the nation our share of the trade of the markets of the world. The foreign trade of the United States is now valued at four and one-half billion dollars per year, of which two and one-half billion dollars represent exports. This trade has developed largely by reason of our natural resources and the individual enterprise of American industry, but without an American merchant marine, comprehensive national policy, or commercial and industrial coöperation. It is for this that the council has been created, and it is hoped that something tangible may result.

SANITARY CONDITIONS ON THE RAND

The spread of vocational diseases among the mine workers of the Rand and other parts of the world has led to the serious investigation of causes and has resulted in an organized effort to reduce mortality and increase the efficiency of the working force. The report of General W. C. Gorgas on South African conditions presents many interesting features and the recommendations made are of a general nature and adaptable to other regions than South Africa. The death rate for the natives employed in the mines of the Transvaal during the year 1903 was 71.7 per thousand. This has been reduced to 26.84 in 1912, but is still very high. The death rate among the negroes employed on the Panama canal in 1912 was 10 per thousand. An examination of the reports of the Native Affairs Department for 1912 shows the four diseases which contributed most to the death rate were pneumonia with 9.8 mortalities per thousand, phthisis 5.4, meningitis 1.3, and enteric fever 1.1, each of which diseases is in some degree infectious and contractable. If they could be eradicated, the death rate from disease for 1912 would have been 5 per thousand. While this is not possible at present, it is highly probable that by proper hygienic measures a very appreciable reduction can be accomplished.

Statistics show that the recently arrived native is much more susceptible to pneumonia than the older workers, which indicates that the matter of immunity is most important. This condition is similar to that obtaining at Panama, where it was found that the death rate was four and one-half times greater among the men who had been on the Isthmus less than three months than it was among those who had been there longer. The decline in the death rate from pneumonia was coincident with allowing laborers to leave the barracks provided by the Commission and build cabins on the hills or to live in the towns of the Canal Zone, and have their families with them.

Overcrowding plays just as important a part in the spread of tuberculosis of types other than pulmonary as it does in pulmonary, and the same methods of control are applicable. Careful routine medical examination of the laborers should be made and disinfection of the dwellings is also important. With native labor the most important measure is the providing of individual quarters. The disease can be particularly combatted by fresh air, sunshine, cleanliness, and roomy quarters.

Miners phthisis, while comparatively unimportant, as shown by the death rate figures published, is nevertheless on the increase. The report for 1903 showed a rate of 0.05 per thousand and in 1912 a rate of 0.10 per thousand. The disease is essentially a silicosis and is caused by particles of silica getting into the lung tissue. This results in a reduction of vitality and increased susceptibility to disease. The hygiene of the disease is obvious, that of laying the dust so that the particles of

silica will not be floated in the air. Cerebro spinal meningitis, which at times causes considerable mortality among the native miners, is an infectious disease which is also best combatted by cleanliness, air, light, disinfection, and the provision of more adequate quarters for the laborers.

The most serious sanitary defect on the Rand is the manner of housing the native. The quarters are too crowded, each native having but 200 cubic feet of air space, which results in the air becoming vitiated. The crowding forces the occupants into close personal contact and therefore largely increases the spread of infectious disease, which applies particularly to pneumonia, tuberculosis, and cerebro spinal meningitis. It is therefore to be urged that the natives be housed in individual buildings and allowed to have their families with them, and if this is not feasible at present, the nearest approximation to it should be attempted. This, General Gorgas thinks, would probably reduce the death rate from 15 to 2 per thousand. A striking coincidence in this respect is the fact that where the natives on the Rand are living as they do on the Isthmus the health rate is approximately as good. In the opinion of General Gorgas this method of housing the natives would materially reduce the recruiting cost, which at present amounts to about £1,000,000 per year, in that with family quarters in place of the compounds a permanent force of skilled workmen would be available. While this would probably be true to a limited extent, it could hardly be expected that the average native who has been transplanted to the mines will become a fixture.

The compounds everywhere show neatness, cleanliness, and commendable care and discipline, but the interior of the native quarters shows the opposite most usually. This is largely due to the fact that authorities do not wish to interfere to such an extent as to cause the natives to become dissatisfied. It is not possible to make any great improvements as long as the men are in such crowded quarters and are allowed to eat and keep food in their sleeping quarters. Each native should be allowed 50 square feet of floor space and be furnished with an individual bed and box in which to keep his belongings and no food or utensils of any kind should be allowed in the dormitories, eating sheds being erected instead.

The report is replete with valuable data and recommendations regarding the local conditions. The record of the Isthmian Department of Sanitation, which in no small degree was responsible for the successful accomplishment of the Canal, is so well known as to require no comment, and if the experience of General Gorgas at Panama can be applied to the Rand and the communities which have similar problems to work out, a great good may be effected. This one branch of the welfare movement has been productive of excellent results in many of the industries outside of mining, and it is to be hoped that the impetus given the work on the Rand may be productive of results not only in South Africa, but in other parts of the world as well. The subject is one which is overlooked by the average operator, but is well worthy of attention from both a humanitarian and efficiency standpoint.

THE INSTITUTE AND CONGRESS

Projects for the revision of the mining laws have, incidentally, reacted in a number of directions. For example, it has made it necessary for the American Institute of Mining Engineers to face squarely the matter of whether it can or cannot make recommendations as to legislation affecting mining. It is evident to anyone familiar with the situation that Congress often needs disinterested advice as to technical matters, and it is equally well known to those who know Congress and the Congressmen that authoritative opinions from truly representative bodies would be welcomed by the real leaders. There are so many public bodies addressing Congress, and it has been shown repeatedly that it is so easy for adroit manipulators to secure favorable action on any project from a body that does not assume responsibility, that volunteered advice is at a heavy discount. At the same time a real expression of opinion from the American Institute of Mining Engineers would deserve, and would carry, great weight. The difficulty is to secure any such consensus of opinion. The proposed creation of a commission to codify and recommend revision of the mining laws, has attracted great interest among mining men and, following the thorough discussion of the matter at the New York meeting of the Institute a committee was appointed to further the project. We believe that there would be no material dissent from the proposal to create such a commission if the individual vote of each member of the Institute had been taken since, while, there are wide differences of opinion as to what revision is necessary, there is general agreement that the laws need mending and that preliminary consideration by a competent commission will be helpful. However, strict constructionists raised a question as to the authority of the Directors of the Institute to appoint any such committee, and, the matter being referred to counsel, the Directors were advised that, while a committee to recommend appointment of engineers on such a commission was proper, no authority existed for one to urge the creation of the commission itself. An amendment to the constitution has now been proposed so as to make clear the right of the Directors to act in such cases and this amendment is now before the Institute for consideration. Whether it should be passed, opens too large a question for discussion at this time. In general we feel keenly that the Institute has never exerted the influence in public affairs that it could and which would be good for it and for the industry, but before opinions are expressed they must be formulated and that requires development of machinery which the Institute as yet does not possess. The amendment as framed opens the way to what we consider a desirable change, but if adopted it must be supplemented by creation of machinery to give it effect.

Smelting Costs and Prices for Silver-Lead Ores

By L. S. AUSTIN

In the early history of silver-lead smelting in Utah the oxidized ores were smelted and sulphide ores avoided, and so but little matte was made. But when the supply of the easily obtained, surface, oxidized ores fell off, provision had to be made for treating the matte, consequent on the use of the complex sulphides. Heap-roasting of the matte was resorted to, followed later by the building of reverberatory roasters. Practice from that time has been that of the roasting and, recently, the sintering of such sulphides, not only for ridding them of sulphur, but to get them so agglomerated that little or no flue dust would be made. It was also found that by thus sintering or agglomerating, the tonnage of the furnaces was largely increased. Finally, it has become the custom to sinter, not only the sulphides, but the 'fines' of oxidized and silicious ores, these 'fines' constituting commonly about one-third of the whole.

System of Ore Buying

Meanwhile a system of buying ores, based on their mineral and metal contents, came into vogue, and this was gradually modified and added to as experience suggested. A contract for the purchase of ore as now prevailing would be to the following effect:

Gold to be paid for at $19 per oz., but no payment for less than 0.025 oz. per ton. In this case the smelter gains all between this and $20.40 per oz. when it sells its base-bullion.

Silver to be paid for at 95% of the New York quotation for bar silver, but no payment to be made when there is less than one ounce per ton. The 5% deduction is intended to cover the loss in smelting. If an ore is high in slag-forming constituents it may not do so.

Lead is to be paid for at 90% of the New York quotation for market lead, from which shall be deducted 1¼c. per lb. No payment is to be made if there is less than 5% in the ore. The deduction of 10% is to cover the loss of lead in smelting, due not only to the slag carrying off 1 to 1¼% of its weight as lead, but to the volatilized lead. The bag-house today prevents the volatilization loss. No doubt with silicious ores the slag loss may be exceeded. The deduction of 1¼c. per lb., or $25 per ton, is to pay for freight and treatment. Under head of 'freight and refining costs' it is shown that this cost is $18 only. The non-payment for less than 5% lead is a relic of days when lead was not so closely saved.

Iron to be paid for at 7c. per unit if the lead contents are over 30%; when from 30 to 25%, at 6c. per unit; under 25% lead, at 5c. per unit. Iron is paid for because of its fluxing value. The higher value set on it when the lead content is higher, is to encourage the shipper to maintain that content. It has been realized by the smelting companies that the higher the lead the lower the slag-forming content of the ore. It is also quite possible that the company may be short of lead, which, as a collector, must be maintained to a certain ratio of the charge, preferably 10% at least.

Insoluble (impure silica) is charged for at 12c. per unit. The insoluble content is more easily determined and is higher than the actual silica, and so gives an advantage to the smelter. The charge of 12c. per unit is made because the silica must be smelted, not alone with the addition of iron worth 5c. to 7c. per unit, but also limestone at 90c. per ton.

Zinc, when less than 5%, has no charge against it, but over that figure the excess is charged for at 2c. per unit. Zinc, especially as blende, goes in part into the matte, in part into the slag, and in part is volatilized, making trouble in the shaft of the furnace, and carrying off some silver. With the bag-house it is believed that no silver is lost. However, due to its making trouble, it has been penalized when, as in this case, it exceeds 5 per cent.

Arsenic forms speiss, and this latter, when in excess of 5%, is charged for at 20c. per unit. When a furnace is reducing well, speiss forms. It carries some silver and gold, and hence must be re-treated. Whether 20c. per unit is a just charge or not is an open question: it is a suspiciously round number.

Sulphur is charged for at 25c. per unit up to a maximum of $3 per ton. It has been assumed that $3 is to cover the cost of roasting an ore of 12% sulphur or over. If an ore contains to exceed 2 to 4% sulphur, it may well be sintered at a cost of 75c. per ton.

A treatment charge of $1 per ton is made for an ore of 30% lead. For each unit of lead over 30% a credit of 5c. per unit is allowed, and for each unit of lead under 30% a charge of 8c. per unit is made. It is evident that the lead in the ore is greatly desired; also, as the percentage of lead increases, so the silica decreases, with a less production of slag. The figure of $1 per ton for treatment, as will later appear, is less than the actual cost, and this is done in place of giving the full price for the lead. It is thought this makes it appear more satisfactory to the shipper.

Costs Under Ideal Conditions

The present paper is confined to the discussion of a method of estimating costs and prices of ores treated in the silver-lead custom plants of Utah, for a works where the flue dust from both sintering machines and the blast-furnaces is caught in a suitably constructed bag-house, and having an equipment suited to obtain low operating costs. It also implies that it is possible to obtain ores in such proportions that it is necessary to carry neither a low percentage of lead on the charge nor to buy ore for fluxing.

The chief cost factors involved are: smelting cost; roasting and sintering; re-treatment of matte; smelting limestone flux; slag-forming content; metal losses; iron or silica excess; profit; metal values.

Smelting Cost per Ton of Charge.—It is difficult to obtain present-day costs, and accordingly an illustrative estimate, based upon published figures, and hence open to correction, is here given. The following costs per ton of charge are assumed:

Labor	$0.500
Coke, 12½% at $7 per ton	0.875
Fuel for power	0.120
Lime for coke-ash	0.015
Maintenance and repairs	0.400
Delays (accidents, strikes, railroad)	0.100
Flue-dust recovery	0.040
Administration	0.160
Smelting per ton of charge	$2.210

This figure differs from that often quoted in cost estimates in which the items are differently distributed. It is assumed that whether the ton of charge is of ore alone, as in the case of a self-fluxing ore, or of ore and fluxes together, the same percentage of fuel is to be used—a matter worthy of further investigation. Certainly a silicious ore should take more fuel than one high in lead.

Assuming the slag content at 70% of the charge, the cost per ton of slag becomes \$2.21 ÷ 0.70 = \$3.16.

Roasting and Sintering.—It is good practice to screen out the 'fines' from a sulphur-free ore, and, before blast-furnace treatment, to sinter it. This fine material is assumed to constitute one-third of the run-of-mine ore. In the case of a concentrate, all would have to be sintered. An ore, carrying a minimum of 2 to 4% sulphur, should be sintered, and therefore all of it should be crushed. Ores high in sulphur are rough roasted in one of the multiple hearth roasters, such as the McDougall, the Wedge, or the Herreshoff, then sintered on a machine of the Dwight-Lloyd type. The figure of 75c. per ton is intended to cover both. When a sintered ore, still containing 4% sulphur, is smelted, it may be computed that 2% enters the slag and is volatilized, leaving 2% to form 10%, or 0.10 ton, of matte per ton of ore, which, as given below, costs \$0.334 to re-treat.

Matte can be sintered, and re-treated like an ore. The estimate for so doing will be:

Rough roasting and sintering	\$0.75
Crushing, sampling, and assaying	0.18
Re-smelting	2.21
Metal loss on 0.75 ton at \$0.92	0.69
Profit per ton	0.86
	\$4.69
Less 38 units available iron at 6c	2.28
	\$2.41
Re-treating 0.25 ton matte	1.17
	\$3.58
Less 4 units available iron at 6c	0.24
	\$3.34

Smelting Limestone Flux.—The amount of limestone depends upon the quantity of silica carried by the ore. It is an inevitable charge against the ore, and not only must the limestone be smelted, but it must be paid for. The cost per ton of limestone is:

Smelting cost	\$2.21
Cost of limestone	0.90
Iron to flux 4% SiO_2 = 3.1 units at 6c	0.19
	\$3.30

In a slag of SiO_2, 33%; FeO, 33%; CaO, 20%; ZnO, 8%; the ratio of SiO_2 to CaO is as 1 : 0.6, or, since limestone is approximately 50% CaO, the ratio of silica to limestone will be as 1 : 1.2.

Slag-forming Constituents.—These vary with the ore, being roughly equal to the silica plus the unreduced bases. Thus a ton of a roasted ore of the composition PbO, 22%; CuO, 0.3%; ZnO, 20%; Fe_2O_3, 33.3% (FeO, 25.9%); As_2O_5, 1.1%; Al_2O_3, 1.8%; CaO, 2%; MgO, 0.5%; SiO_2, 17.4%; S, 3.6%; would have for slag making 0.676 ton of silica and bases. Strictly speaking, this slag would carry 1% Pb and 1 to 1.5% S; while some of the zinc would be volatilized. Possibly the gain to the slag in lead and sulphur would be compensated for by the loss in zinc.

Now, in silver-lead smelting the losses in lead and silver increase proportionately with the increase of slag-forming constituents of the ore itself, plus an addition due to the presence of silica; and silica must be fluxed, not only by the iron of the charge, but limestone must be added. Thus for 33% silica must be added enough limestone to insure the presence of 20% CaO or 0.6 of the silica. For one ton of the roasted ore just cited, the figure 0.676 + (0.174 × 0.6) = 0.78 ton would accordingly be obtained, and this may be called 'the corrected slag content.' Since in practice it is not expected to make a complete analysis of each ore, the question arises, what can be done to obtain its slag content? A laboratory determination (using ammonium nitrate to aid oxidation if necessary) would give the weight of the well roasted ore and the loss of weight in roasting, as a basis for calculation.

Take for example an oxidized lead ore containing Pb, 39.2%; Fe, 16.4%; SiO_2, 8%; Zn, 1.6%; S, 1.3%; with 17.3 oz. Ag and 0.05 oz. Au per ton. Upon ignition and roasting, there is a loss of 16%, leaving per ton:

Weight of roasted ore		0.840 ton
Less PbO	0.425 ton	
Less Fe_2O_3 to FeO (14%)	0.023	
		0.448 "
		0.392 "
Add, due to silica, 0.08 ton × 0.6		0.048 "
Being 44.0% of 'corrected slag content'		0.440 "

Assuming that the loss of lead in smelting is 1%, and for silver 0.6 oz., per ton of slag produced, then:

880 lb. by 1% = 8.8 lb. lead at 3.1c	\$0.273
0.44 ton slag by 0.6 oz. = 0.264 oz. at 50c	0.132
Loss due to slag	\$0.405

Metal Losses.—To the actual cost of smelting should therefore be added the loss above computed. On the other hand, in any completely equipped plant, a deduction of 1% of the total gold, silver, and lead would be made to cover refinery losses and 1½% for the tie-up of metals for three months at 6 per cent.

Iron or Silica Excess.—The composition of a slag well suited to Utah conditions has already been given, namely, SiO_2, 33%; FeO, 33% (Fe, 25.7%); CaO, 20%; ZnO, 8%. The ratio of SiO_2 to Fe is as 1 : 0.77, hence the estimate on an ore, as in Case II, carrying SiO_2, 63.6%; Fe, 3.5%; CaO, 0.8%; is as follows:

Iron for silica, 63.6 × 0.77	49.0
Iron (and lime) in the ore	4.3
	44.7

This at 6c. per unit, which is what is to be paid for in case of an ore carrying an excess of iron, will be 44.7

× 6c. = $2.68. Where an iron-bearing ore can be bought with a lower figure than 6c. per unit for the iron, the silicious ore can be smelted cheaper, and so the smelting company can vary its payments for iron to suit its needs. The cost for smelting limestone is given as $3.30 per ton—approximately 6c. per unit.

Profits on Treatment.—On an investment of $2,000,000 for plant and equipment, and of $1,000,000 of working capital, to make a profit of 10% (which, considering the risks, is a fair return on the investment), a company producing 1000 tons per day, or, allowing 5% for delays, 347,000 tons of charge per year, should make 86c. per ton of charge put through the furnaces. Now in Case 1 below there is put through 1.492 tons, which at 86c. should give a profit of $1.28, or a total treatment charge of $8.66; and for Case II, similarly calculated, a charge of $10.31 per ton.

Factors Modifying Profits

Where operations proceed smoothly, where the slag losses are no greater than those given for good smelting, where small amounts of gold and copper are not paid for, and where skill is employed in the sale of the metals produced, profits may become greater than above specified. On the other hand, if iron must be purchased for fluxing, if the market for metals is a falling one, if it is not possible to get the best combination of ores for profitable smelting, these profits may be greatly diminished.

Freight and Refining Costs.—Where the smelting company has no greater investment than that of its smelting plant and operating fund, and has to sell its base-bullion, a favorable contract for this sale would be as follows:

1. A contract for a specified term and for a production, in the case of our typical works, of 100 tons per day, or of 3000 tons of base bullion monthly.
2. Gold to be paid for at $20.40 per ounce, but no payment for less than 0.05 oz. per ton.
3. Silver to be paid for at 99% of the New York quotation for bar silver, but no payment for less than 3 oz. per ton.
4. Lead to be paid for at 99% of the wet assay on the New York quotation for market lead.
5. Freight (Utah to New York), per ton $12
   Treatment 6
   $18

The buyer agrees to advance 90% of the calculated net value, charging at the rate of 6% for such advanced payments.

Deductions for Metal Contents.—Now, if the smelting works is to make its profit on the treatment of the ore, and not on the gain between what is received and what it pays for metals, it will be found that when lead was 4c. per lb. or $80 per ton in New York, the payment for the lead should be (99% of $80) −$18 = $61.20, or 61.2c. per unit. For the silver, in the same way the price per ounce would be 49.5 cents. As a matter of fact, this method is not followed. The general way, as already shown, is to make a deduction of 10% from the lead and of 5% from the silver, and to say that it is due to losses in smelting; also to deduct from the lead present at the rate of $20 to $30 per ton.

Where competition exists, as it does in Utah, these deductions are, it is true, retained, but the profit thus made is applied to reduce treatment charges. Nor is competition the only factor; to obtain desired ores and to obtain those on which the compensation to the miner is small, prices are made on such ores as will bring them to the works. As prices are now quoted by the different companies, but little money is made in smelting. What is made comes from profits in other parts of the country, from the profits in refining, and skill in the sale of metals in the New York market.

Illustrative Examples

To apply the foregoing enumerated factors, four cases may be discussed in detail:

Case I.—This is a lead ore containing Pb. 30%; SiO_2, 41%; Fe, 2.8%; Zn, 0.9%; CaO, 0.9%; S, 5.2%; with Ag, 9.9 oz. and Au, 0.025 oz. per ton. The costs and returns will be:

Smelting cost		$2.21
Crushing, sampling, and assaying		0.18
Sintering		0.75
Re-smelting 0.10 ton matte		0.33
Smelting limestone, 0.41 ton SiO_2 × 1.2 = 0.492 ton × $3.30		1.62
Slag-forming contents:	Ton.	
Roasted ore (laboratory result)	0.870	
From limestone 0.41, SiO_2 × 0.6	0.246	
	1.116	
Less Fe_2O_3 to FeO 14% of 0.028	0.004	
PbO	0.324	
	0.328	
Total	0.788	
Slag losses:		
Lead, 15.8 lb. at 3.1c	$0.49	
Silver, 0.788 ton × 0.6 × 50c	0.24	
		0.73
Fe needed for SiO_2:	Units.	
41% × 77	31.6	
Less Fe and CaO	3.7	
	27.9 at 6c.	1.67
Profit on 1.492 tons at 86c		1.28
Total charges		$8.77
Metal values:		
Pb, 600 lb. at 3.1c	$18.60	
Ag, 9.9 oz. at 50c	4.95	
	$23.55	
Less 2½%	0.59	
Net metal values		$22.96
Charges		8.77
Net returns		$14.19

Case II.—This is a silicious leady ore of the following composition: Pb. 28.5%; SiO_2, 63.6%; Fe, 3.5%; Cu, 0.05%; Zn, 0.8%; CaO, 0.8%; S, 2.1%; Ag, 30 oz. and Au, 0.0035 oz. per ton. The costs and returns are:

Smelting cost		$2.21
Crushing, sampling, and assaying		0.18
Sintering ⅓ ton at 75c.		0.25
Smelting limestone flux, 0.636 ton SiO_2 × 1.2 = 0.76 × $3.30		2.51
Slag-forming constituents:	Ton.	
Roasted ore (by laboratory test)	0.970	
Limestone, 0.6 × 0.636	0.382	
	1.352	
Less Fe_2O_3 to FeO, 14% × 0.035	0.005	
PbO	0.308	
	0.313	
Total	1.049	
Lead loss, 21 lb. at 3c.	$0.65	
Silver loss, 1.049 × 0.6 × 50c.	0.32	
		0.97
Profit on 1.76 tons at 86c.		1.51
Iron flux needed (77% × 63.6) −4.3 = 44.7 units at 6c.		2.68
Total charges		$10.31
Metal values:		
Pb, 570 lb. at 3.1c.	$17.67	
Ag, 30 oz. at 50c.	15.00	
Au, 0.035 oz. at $20.40	0.71	
	$33.38	
Less 2½%	0.81	
Net metal values		$32.57
Charges		10.31
Net returns		$22.26

Case III.—This is an iron-bearing ore with iron excess, of the composition: Pb, 5.8%; SiO_2, 16%; Fe, 31.8%; Mn, 10.6%; Zn, 4%; CaO, 2.1%; S, 0.6%; with Ag, 4.5 oz. and Au, 0.01 oz. per ton. The costs and returns are:

Smelting cost		$2.21
Crushing, sampling, and assaying		0.18
Sintering ⅓ ton at 75c.		0.25
Smelting limestone flux, 0.16 ton SiO_2 × 1.2 = 0.19 ton × $3.30		0.63
Slag-forming constituents:	Ton.	
Roasted ore by laboratory test	0.900	
Limestone, 0.6 × 0.16 SiO_2	0.096	
	0.996	
Fe_2O_3 to FeO, 14% × 0.424	0.059	
PbO	0.063	
	0.122	
Total	0.874	
Lead loss, 17.4 lb. at 3.1c.	$0.53	
Silver loss, 0.87 × 0.6 × 50c.	0.26	
		0.99
Profit, 1.19 tons at $0.86		1.10
		$5.36
By iron excess, 42.4 (77% × 16.0) = 31 units at 6c.		1.86
		$3.50
Metal values:		
Pb, 116 lb. at 3.1c.	$3.60	
Ag, 4.5 oz. at 50c.	2.25	
Total	$5.85	
Less 2½%	0.15	
Net metal values		$5.70
Charges		3.50
Net returns		$2.20

Case IV.—This is the oxidized lead ore quoted under 'Slag-forming Constituents.' The figures are:

Smelting basis		$2.21
Crushing, sampling, and assaying		0.18
Sintering ⅓ ton ore		0.25
Smelting limestone flux, 0.08 ton SiO_2 × 1.2 = 0.096 × $3.30		0.32
Slag-forming contents = 0.44 ton.		
Lead loss, 9.6 lb. at 3.1c.	$0.27	
Silver loss, 0.473 ton × 0.6 × 50c.	0.13	
		0.40
Profits, 1.096 tons at 86c.		0.94
		$4.30
By iron excess, 16.4 (77% × 8) = 10.2 × 6c.		0.61
		$3.79
Metal values:		
Pb, 764 lb. at 3.1c.	$23.68	
Ag, 17.3 oz. at 50c.	8.65	
Au, 0.05 oz. at $20.40	1.02	
	$33.35	
Less 2½%	0.83	
Net metal values		$32.52
Charges		3.79
Net returns		$28.73

Contract Specifications

To simplify the method of paying for an ore under contract, which may vary within a considerable range in silica, iron, and sulphur, I would propose the following charges and prices per ton:

Preliminary Treatment

For crushing and sampling	$0.15
Assaying and testing	0.03
Total	$0.18
Where the ore must be sintered, an additional charge:	
For sintering	$0.75
For re-treating matte	0.33
	1.08
Total	$1.26

If the 'fines' only are to be sintered, the charge for sintering them is 25c. to 75c. per ton, according to their percentage.

Per Ton of Slag-Forming Contents

For smelting		$3.16
Slag loss:		
20 lb. Pb at 3.1c.	$0.62	
0.6 oz. Ag at 50c.	0.30	
		0.92
Profits		1.23
Or per pound 0.26 cents		$5.31

Per Ton of Silica

For iron, 77 units at 6c.	$4.62
Limestone, 1.2 tons at $3.30	3.96
Slag loss, 0.72 tons at 92c.	0.67
Profits, 0.6 ton at $1.23	0.74
Or per unit 9.85 cents	$9.99

The lead is not to be deducted from the slag-forming contents. To compensate for this, from the freight and refining cost should be subtracted the cost of smelting it, namely, $3.16

per ton of PbO or $3.40 per ton of lead. This leaves $14.60 per ton, or 0.73c. per lb., to be taken from the New York price of lead.

Taking Case I for example, the costs on this basis would be:

Preliminary treatment	$ 1.26
Slag-forming contents, 0.87 ton at $5.31	4.67
41 units SiO_2 at $9.99	4.10
	$ 9.97
Less 3.7 units (Fe and CaO) at 6c	0.21
Net costs	$ 9.76
Metal values:	
Pb, 600 lb. at 3.27c	$19.62
Ag, 9.9 oz. at 50c	4.95
Total	$24.57
Less 2½%	0.62
Net metal values	$23.95
Charges	9.76
Net returns	$14.19

The result is the same as in the first method, but the calculation is simpler.

Smelting companies do not take the public, or rather the shippers, into their confidence. The smelter knows how much profit he is going to make on any ore, while the producer or shipper is often ignorant regarding details, is suspicious, and complains that he is charged an undue price for the treatment of his ore. The ore-buyer gives no figures to reassure the seller; indeed, he must generalize, and were he too frank, would be admonished. Smelting company reports reflect this. They give information in a guarded way. The companies would be willing to give information were it to their stockholders only, but if it were divulged the shipper and the competitor would take advantage of it. Indeed, the shippers are often shrewd, well posted men. To give them details would mean that they would see the weak points of the buyer. The buyer, by a complicated system of prices, discounts, and penalties, casts an air of mystery around the transaction, and adds to it by making contracts on different systems. In consequence, he is profoundly distrusted, so that when, as at present, the smelting company is making little or no money, its statements are not believed, though true. Bad feeling exists where it should not, brought about by a policy of concealment. It is my purpose, as an independent engineer, to try to dispel some of this unfortunate antagonism.

I believe that in this paper I have set forth a fundamentally more rational way of estimating costs and fixing prices for ores. Indeed, the question of costs, a very extensive one, should be recast upon newly acquired data owing to recent changes in smelting methods. Attention has been chiefly confined to those metals and associated minerals affecting the general problem of smelting, without undertaking to estimate the value of lesser factors, such as small amounts of copper and gold, or the effect of zinc, antimony, arsenic, bismuth, and tellurium on the furnace charge.

The Three R Mine, Patagonia District, Arizona

By F. R. PROBERT

A pioneer of Santa Cruz county, Arizona, R. R. Richardson, of Patagonia, has held for many years a group of claims on the slopes of the Patagonia mountains known as the Three R property. Few properties have suffered the condemnation of competent engineers that this has been subjected to; fewer still have been as frequently examined. The Three R was almost a joke among the engineers of Arizona, and as each passed judgment it was recorded in Mr. Richardson's files, which today make interesting reading. The opinions of upward of twenty engineers of good repute are catalogued with such comment as the owner fancied would fit the findings. 'Turned down cold,' 'No good,' 'Reported unfavorable,' and the like are penned to the name of the engineer with date of visit. My own name appears on the list, July 1908. The reason for all this is readily explained. Large 'low-grade' coppers have been the fashion of recent years, and the Three R property was studied from this viewpoint; the possibilities of high-grade ore-shoots in a lean pyritized mountain mass were not considered, and had it not been for the chance finding of enriched ore by continuing an adit, which for nearly 600 ft. was in barren hard rock, it is likely that the list of 'experts' would be considerably larger than it is and the comment of the owner more forceful. Two years ago, N. L. Amster, of Boston, took a lease and bond on the property, and after careful geological investigation proceeded systematically to explore the more attractive ground. He has shipped to date approximately 30,000 tons of ore averaging 9% copper. The claims are about nine miles south of Patagonia and nineteen miles northeast of Nogales, stations on the branch line of the Southern Pacific system south of Benson, Arizona. The nearest railroad point is Bloxton, 3.7 miles west of the mine.

The Patagonia mountains are a continuation of the Santa Ritas, south of Sonoita creek. Copper, zinc, lead, gold, and molybdenum deposits have been prospected. The Three R property is situated on the northwest slope of the Patagonia mountains, and is characterized by a particularly rugged surface. The bold escarpments and prominent ridges are due largely to the relative resisting power of different igneous rocks, or phases of the same rock, to erosion. A depression once initiated would be rapidly worn by the scouring action of rock and water during the short-lived deluge of summer rains. The steep slopes cause a rapid run-off of all waters, and the rocks being dense compact masses showing little or no cleavage or jointing, would allow of but little of the oxygenated waters to seep far below the surface, except in fairly open fissures. Only igneous rocks are represented in the immediate neighborhood of the Three R mine, but inasmuch as similar rocks

FIG. 1. THREE R MINE, LOOKING EAST.

are intruded in Paleozoic sediments at the property of the Helvetia Copper Co., I tentatively classify the rock of greatest economic importance as being post-Carboniferous, probably late Tertiary. The youngest rock, alaskite, is the most widely distributed. It forms the greater part of Three R mountain. In the fresh state, it is a coarse-grained macrocrystalline aggregate of quartz and alkali feldspar, orthoclase, with occasional biotite plates. In all exposures, whether fresh or in an advanced state of feldspathic alteration, the large blebs of quartz stand out conspicuously. Aplitic phases of the alaskite occur as silicious ribs in the parent rock, but have no economic importance. As alteration proceeds, the feldspars become earthy, and according to the amount of the original pyritization are white, brownish, or deep red, the quartz remaining unchanged. The alteration products of the feldspars are sericite, kaolinite, and alunite. This latter mineral is found not only in the vicinity of the chalcocite orebodies, but in altered pyritized areas, where the rocks have been more or less cleaved. F. C. Schrader, in *Economic Geology* (December, 1913), attributes the formation of alunite at the Three R mine to metasomatic replacement of the orthoclase by hydrothermal solutions ascending fissures following the intrusion of the mass itself or of later volcanics. Post-volcanic metamorphism is evidenced by silicification and cupriferous pyritization of the shattered rock near the main fractures, but the close relationship between chalcocitization and oxygenation of sulphides suggests a later origin of the alunite. I attribute it to the sulphurous waters of the oxidized zone. Alunite is by no means an uncommon associate of enriched copper ore. At the Ray Central mines it was found in the intrusive sheets of ore-bearing granite porphyry; and again at the Shannon and Ryerson mines of Metcalf and Morenci, I have noted it in the pyritized altered porphyry.

The alaskite is intrusive in the older trachyte and rhyolite (feldspar and quartz) porphyries, which are widely scattered. They occur as a series of isolated blocks in the alaskite without any visible connection one with the other near the Three R mine, although to the north, Red mountain and the adjoining hills are made up entirely of these older porphyries. The trachytic variety is the more common, and its dull white mottling makes it readily distinguishable both in the field and underground workings. The porphyries are strongly acidic, granular to aphanitic in texture, with distinguishing phenocrysts.

The intrusion of the alaskite caused little or no apparent alteration of the older porphyries. Chilled surfaces show as granular, even glassy phases, but a typical change is not noticeable as a direct result of the action of the younger on the older rock. The after effects of the alaskite intrusion seem to have a direct bearing on the economic importance of the property under consideration. Hot aqueous emanations from deep seated sources along lines of fracture and rock weakness initiated the mineralization, which by later processes has made ore. The sulphurous metallic contents have been deposited as cupriferous pyrite and associated minerals, along lines of weakness, and this primary mineralization has been converted locally, by metamorphic change due to oxygenated waters, into the orebodies now being mined.

While the igneous rock massif does not show any regular system of joints or cleavage planes, there are definite lines of fracture and faulting along which all ore of commercial value has so far been found. Underground, these fractures are sharply defined and readily followed, often being characterized by a clay seam several inches wide with variable amount of cupriferous pyrite and chalcocite concentrated in or near the fracture, and gradually diminishing in copper content on either side. The fractures penetrate all three of the recognized rocks. The work to date shows that the largest orebodies are found under an outcrop where the pyrite has been completely oxidized to earthy hematite and where the rock is more abundantly cleaved, the cleavage planes being filled with the rusty residuum of original sulphides.

The whole district in an area of three or four square miles is so heavily iron stained at the surface that in its broader aspects, it resembles the properties of the

so-called low-grade porphyry copper mines of Arizona. The rocks are pyritized throughout, but owing to the lack of shearing, cleavage, or jointing, the oxidation of these sulphides is very limited in depth except along the major breaks. The hematite outcrops of the stronger fractures are seldom copper stained. Oxidation is complete, but lenses of locally enriched ore are found below. The outcrop of the *B*, Fig. 2, fracture shows massive black botryoidal limonite; that of the *D* shows as a bright red ochreous stain. The Three R fracture shows limonitic casts of pyrite in an extremely sericitized alaskite with occasional small masses of bornite enveloping original pyrite. At the *D* fracture oxidation of copper glance has resulted in metallic copper, while azurite and malachite are later oxidation products of the previously enriched mineral. The ore now being mined is all secondarily enriched. It consists of copper glance, both massive and disseminated, occurring in shattered area of alaskite or porphyry, on either side of one of the major breaks.

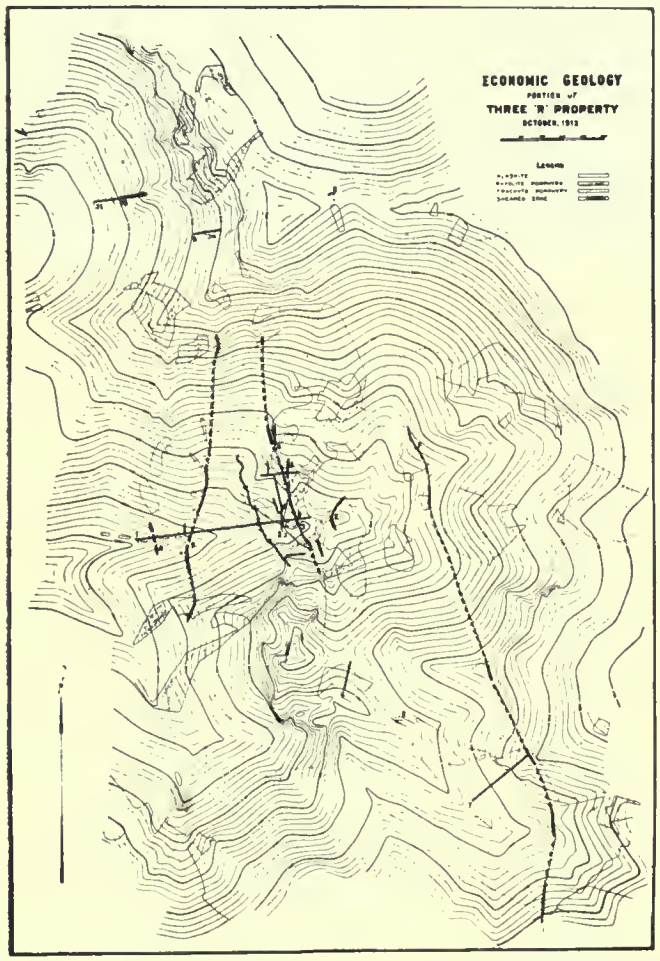

FIG. 2. THE RHYOLITE PORPHYRY AND TRACHYTE PORPHYRY FORM PATCHES AS OUTLINED IN THE ALASKITE.

The main orebody of the *C* fracture, which has been extensively stoped, was indicated by a meagre hematite outcrop on the surface in a slightly crushed area. Approaching it underground, the alaskite is veined with secondary quartz and quickly changes from the normal pyritized rock to an altered alaskite heavily impregnated with copper glance. Masses of pure glance several feet across are found, the high-grade lens being at the main adit level (215 ft. below the surface) 37 ft. wide. The horizontal limits of the orebody are marked only by the change in value, not by any structural detail. This orebody has been followed a vertical distance of 500 ft., with high-grade ore still showing in the bottom of the winze. The stopes extend to within 40 ft. of the surface, where the glance slowly fades into the ochreous hematite. On the foot-wall side of the stopes, the chalcocite is finely disseminated around bright glistening pyrite grains in a soft sericite felt. The centre of the orebody is more completely alunitized and sectile slabs and masses of pure glance have the appearance of a conglomerate, so striking is the black and white contrast of mineral and gangue. On the hanging wall side perfect stubby octahedra of pyrite, two and three inches across, are found coated with a thick film of chalcocite (Fig. 3). The compact masses of pyrite are but surficially altered. On the 500-ft. level, 110 ft. below the surface, stope No. 100, the pyrite was found coated with covellite of a purplish blue color, while on the Three R claim, bornite envelopes the crystal faces of pyrite. The high-grade ore is always found in close proximity to the major fractures and fades gradually into non-commercial unaltered pyrite on either side. Where the cupriferous pyrite is definitely crystalline it is but coated with chalcocite; enrichment seems to advance with distortion or crushing of crystal forms. L. C. Graton describes several slides made of Three R ore in his discussion of the 'Sulphide Ores of Copper.'* His further research along these lines will be awaited with interest, particularly as to the nature of unenriched portions of sulphide deposits in an ore horizon.

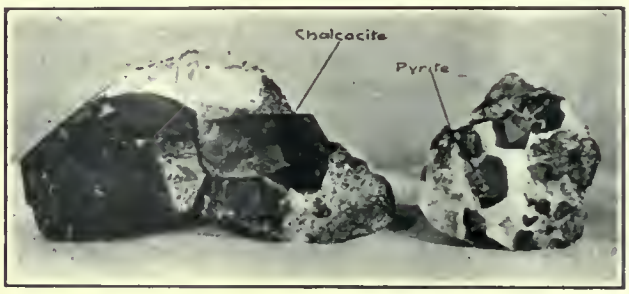

FIG. 3. PYRITE CRYSTALS COATED WITH CHALCOCITE.

Other small lenses of high-grade ore have been exposed by drifts along the main fractures, but their distribution is very erratic between high-grade shoots. The rock on either side of the fault fissure contains disseminated chalcocite, 3 to 4% ore, which may later be mined and milled.

COAL PRODUCTION of Montana in 1913 was 3,240,973 short tons valued at $5,653,539, a record for the state. There were 3630 men employed, of whom 20 were killed, and the average coal broken per man-year was 893 tons.

*Trans. Amer. Inst. Min. Eng., May 1913.

Dredge Construction in Portuguese East Africa

By CHARLES JANIN

The reeent eonstruetion of a 7½-ft. California type, all steel electrie dredge by the Bucyrus Co., in Portuguese East Africa, is of considerable interest to those connected either with dredge construction companies or with dredge operation. To each, it opens up new possibilities. The Americen dredge builder is slowly but surely invading the foreign field, and with the sueeess attending the operation of first-class dredge equipment, further investigations will be encouraged, and other dredges built. This dredge is one of six California type dredges to be ordered in America for foreign countries.

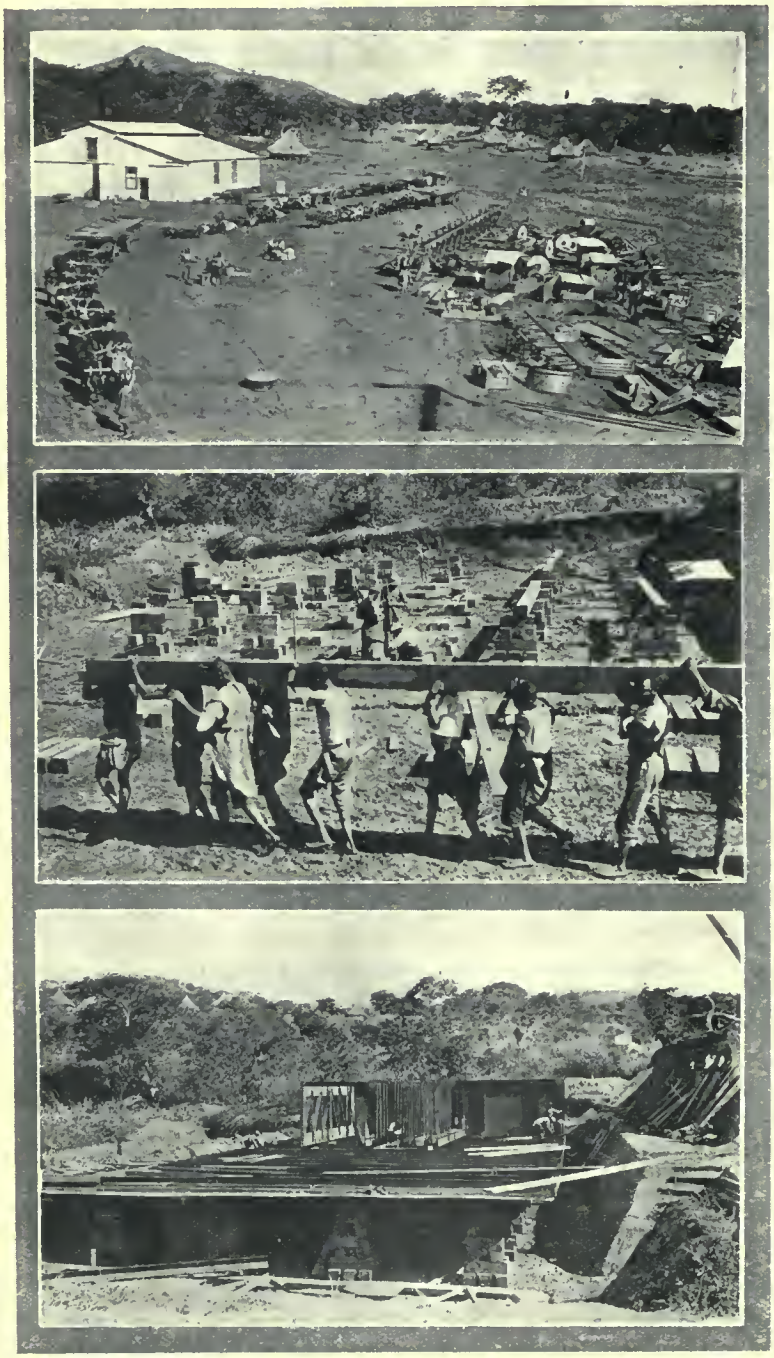
The Kolchan dredge of the Orsk company in East Siberia, which was built by the New York Engineering Co., was the first modern California type dredge to be built in a foreign country. Other California type dredges are the Pato on the Nichi river in Colombia, built by the Yuba Construction Co., two dredges in the Philippine Islands, one built by the New York Engineering Co., the other by the Yuba Construction Co., and a dredge for the recovery of tin for the de Sabla interests near Belmonte, Portugal, designed by the Union Construction Co., and built by Fraser & Chalmers. The latter dredge is the first of American type built for tin recovery in a foreign country. All of these dredges are now operating sueeessfully. In addition to the above, the Marion Steam Shovel Co. has shipped the machinery for a 7-ft. dredge to the Ural district in Siberia. It can be seen that nearly all the American dredge builders are now represented in foreign countries. Without doubt the sueeess of these boats will attract more attention to American dredges, and American builders will be consulted upon proposed installations of any importance.

The Andrada dredge was built by the Bucyrus Co., and was constructed by C. T. Nicolson, to whom I am indebted for most of the information given below. The description of the dredge parts is taken mainly from specifications. It was considered unnecessary to go into more detail for the purpose of this article.

The dredge was constructed entirely of steel, equipped with 68 buekets of 7½ cu. ft. capacity, and arranged to dig 25 ft. below water-level. The dredge was shipped from New York by steamer, the last shipment being March 13, 1913. The point of delivery was Beira, Portuguese East Africa. From this point freight was hauled by the Beira & Mashonaland railway, a distance of about 200 miles, and from the railroad to the property, a distance of eight miles, freight was hauled by means of mule and ox teams. Eight head of oxen, comprising one team, would make a trip one way in three hours. The maximum load for these teams is 3½ tons. To handle the steel spuds and other heavy parts of the dredge, two sets of wheels and axles capable of carrying 25 tons were built and shipped with the dredge. These wheels were 5 ft. in diameter and had a 10-in. face heavily tired. To haul the spuds, whieh were the heaviest pieces of the dredge, 30 mules and 50 oxen were required. The digging ladder, whieh was of the plate girder type, was shipped in three sections.

As is eustomary under conditions prevailing in foreign countries, considerable delay was experieneed in getting freight to the property on aeeount of the poor transportation facilities. All dredge parts were on the ground by June 13, the last delivery being the material that was first required. The dredge pit had been prepared before the arrival of the eonstruetion engineer at the property, and actual eonstruetion began on the 13th day of June. Included in the equipment furnished for construction was a Curtis double compressor, with 35-hp. motor. This was a two-cylinder 10 by 10 vertical compressor, and required only 4 by 6-ft. floor spaee. It gave great satisfaetion and furnished air at 88 lb. pressure for seven riveting hammers, two ealking hammers, and two air-drills. For the machine shop a speeial lathe was taken that eould either handle small work or swing the lower tumbler if necessary. This was arranged by having, with other accessories, blocks to raise the head and tail stoek to any height desired. Power for compressor and pneumatic tools for riveting, whieh was not available until June 16, was furnished by a small plant from an operating mine belonging to the Company. From the time power was available work progressed rapidly in spite of the poor class of labor available, the only delays in construction being for lack of power, which was at times irregular.

The dredge was completed on Oetober 22. After construction was finished, another delay was experienced for lack of power, before the trial run could be made. The hydro-electrie power-plant whieh was being built by the Company independent of dredge construction and which was supposed to be finished before the dredge, was not completed until some time after. When power was supplied, the dredge did good work and was accepted by the Company, at the end of the 30 days trial, according to contract. A bonus given the construetion engineer testified the appreeiation of the management in his work, and their satisfaction with the dredge. Power was generated by a hydro-electrie plant, about 18 miles from the property. Water was delivered at a head of 1000 ft.



through a pipe-line that was something over a mile long.

In addition to the construction engineer, one skilled workman and three winchmen were taken from America, the latter were to remain on the property to operate the dredge, and were used to advantage during construction. Local labor was of the usual floating class of white labor found in Africa, and Kaffirs. Some of the latter made good helpers after being broken in. The largest number of white laborers at one time was 22, and an average of 60 Kaffirs were employed. The illustration showing the crew gives a good idea of the number of men used to build this dredge.

Some difficulty was experienced in teaching unskilled labor the use of air riveting hammers. Inexperienced hands would turn on a full head of air suddenly, and the snaps, which are held in by springs, would fly out like shot from a gun. Several men were injured, and a number had narrow escapes. The proper way to use one of these riveting hammers is to turn on a little air, so as to give light taps at first, in order to spread or swell the rivet in the hole, then full air for finishing the head.

White labor received from 18 to 25 shillings per day; Kaffirs from 20 to 30 shillings per month; all for eight hours work, including Sunday.

Details of Dredge

The hull and housing are built entirely of steel. The hull is 115 by 40 by 9 ft. The plating on the hull is mostly of ⅜-in. steel. The well-hole plating is ½ in. with chafing plates ¾ in. The hull frame is spaced 30 in. centres, with floor beams of 8 by 11¼ in. channels. The deck beams are 6 by 8 in. channels. Vertical members are 4 by 3 in. To provide proper stiffening there are four longitudinal trusses extending from bow to stern. Besides cross-trusses there are two water-tight bulkheads, which divide the hull into four water-tight compartments. The framing of the housing is of structural steel, and the sides are of two layers of light steel plates separated by a layer of pressed paper insulation. The roof is covever with canvas, laid in white lead.

The dredge has a flotation of 2½ feet when fully loaded and operating. Buckets are made in three pieces. The lip is made of manganese steel 13½ in. wide by 1⅝ in. thick in the crown and curved portion, and tapers to ¾ in. thick at the back and lower edges where riveted to the hood. The hood is of nickel chrome steel, with two front eyes about 4½ in. thick, and one back eye about 17¼ in. long with renewable manganese steel bushings about ⅝ in. thick. Bucket pins are of nickel chrome steel 4⅞ in. diameter. The buckets weigh 2250 lb. each. The lower tumbler is six sided, made in two pieces, each piece being a single casting of high-carbon open-hearth steel. The tumbler flanges are circular, and the tumbler faces are faced with manganese wearing plates about 1½ in. thick. The lower tumbler shaft is of forged nickel steel of 10½ in. diameter, bored hollow so that the rod holding the ladder brackets from spreading can pass through it. Journals are run in renewable bearings on the order of the ball and socket joint, completely surrounded by cast steel boxes. The ladder frame is of plate girder type and is approximately 73 ft. long. Ladder rollers are of high-carbon steel 14 in. diameter, spaced about 6 ft. apart. Forged steel shafts of 3¾ in. diameter are pressed into rollers. Bearings are cast steel and designed to keep out sand and grit and pro-

vided with a cavity for lubricating grease.

The upper tumbler consists of a single casting made of basic open-hearth steel. It is six-sided and wearing faces are fitted with renewable manganese steel plates approximately 1⅞ in. thick. The upper tumbler shaft is 15⅞ in. diameter in tumbler, 14-in. journals, and 12$\frac{13}{16}$-in. driving gear. The upper tumbler is driven at both ends through a double train of gearing on the head-frame. The gear trains are driven by a belt from a jack-shaft in the main deck. The gearing is made of open-hearth steel castings, and has machine-finished teeth. The large gears on the upper tumbler consist of gear rims bolted to cast steel spiders. The gear teeth are 2¾-in. pitch by 10-in. face. The pulley for driving the upper tumbler machinery is 44 in. diameter by 24-in. face. The driving pulley connecting the motor with the machinery is 50 in. diameter by 22-in. face. Intermediate jack-shafts are 4⅜ in. diameter. The hopper is of the rock-bottom type, and is built of ¼-in. plate, 3 by 3 by ⅜-in. angles, and lined on the back and sides with ⅜-in. steel plates.

The revolving screen is 5 ft. 11 in. diameter and 35 ft. long and has ⅝-in. perforations. It is carried on two cast steel friction tires with 7-in. width of tread. A spray pipe extending through the interior of the screen is provided with hydraulic nozzles on universal joints, in order to throw water in any desired direction.

The tailing stacker is of the belt-conveyor type 34 in. wide and 60 ft. long between centres of pulleys. The gold-saving tables are of $\frac{3}{16}$-in. steel, and are provided with 1 by 1 by ⅛-in. angle-iron riffles of the Hungarian type. The table area is approximately 1500 sq. ft. The dredge is built to operate both on spuds and head-lines. Each spud is 27 by 36 inches in section, 48 ft. long, and weighs 15 tons.

For the gold-saving table there is one 8-in. double-suction centrifugal pump capable of delivering 2000 gal. per minute against 50-ft. head. For the revolving screen one 10-in. delivering 3000 gal. per minute against 70-ft. head. For hopper and washing bucket one 5-in. with a capacity of 700 gal. per minute against 150-ft. head. There is also one 3-in. bilge pump. All pumps are directly connected to independent motors. In addition to the above pumps, there is a hand pump for priming and cleaning up.

The list of motors is as follows:

	Horse-power.	Speed.
Digging ladder	150	Variable
Winch	25	"
Screen	35	Continuous
Stacker	35	"
10-in. pump	100	"
8-in. pump	50	"
5-in. pump	75	Continuous
3-in. pump	15	"
Total	485	

The transformers are three 200-kw. 50-cycle in 2100 volts, primary to 440 secondary, and one 7½ kw., stepping down from 440 to 110, for the lighting system.

Following are the weights of dredge shipments:

	Pounds.
Steel hull	672,847
Machinery	809,177
Spares, tools, shop, etc.	268,466
	1,750,490

Heavy pieces.	Pounds.
One spud, 27 by 36 in. by 48 ft.	27,860

Heavy pieces.	Pounds.
One spud, 27 by 36 in. by 48 ft.	27,720
Upper section of ladder, 53 by 73 in. by 35 ft.	21,300
Middle section of ladder, 53 by 73 in. by 29 ft.	18,740
Lower section of ladder, 74 by 78 in. by 21 ft.	17,640
Upper tumbler, 55 by 55 in. by 10½ ft.	13,550
Lower tumbler, 64 by 64 in. by 62 ft.	10,370
One revolving screen piece, 64 by 93 in. by 93 ft.	7,500
One revolving screen piece, 43 by 77 in. by 77 ft.	4,450
One lathe, 4 ft. 3 in. by 4 ft. 3 in. by 20 ft. 10 in.	15,758

Details of cost are always a matter of interest, and for that reason I have added the following figures, although in the matter of freight from Beira and of construction cost they are only approximations. They are, however, very near actual cost, which has not yet been officially figured, and close enough for the purpose for which they are given.

First Cost		
Dredge cost f.a.s. steamer New York	$114,500	
Extra parts, erecting, tools, etc.	9,700	
		$124,200
Freight		
Freight to Beira	$ 14,510	
Beira to property (approximate)	15,000	
		29,510
Construction		
Cost of construction (approximate)		27,000
Total cost of dredge ready to operate, including spares, tools, shops, etc. (approximate)		$180,710

Up to the present time gold dredging in Africa has not been a financial success, though a number of dredges have been built and some have operated for years in different parts of the country. The operations of the Andrada dredge will be watched, therefore, with especial interest. There is no question that if the gold content of the ground is as expected, a considerable operating profit will be made, and recent reports from the property are most encouraging for the future.

Ore Treatment at Waihi, New Zealand

The Waihi Gold Mining Co., prior to 1911, had three stamp-mills and cyanide plants, with 40, 90, and 200 stamps, and situated 1, ½, and 5½ miles respectively from the mine. The first, or Silverton mill, was sold in about that year; the second, or Waihi, was shut down in 1912; and the third, or Victoria, was used in 1913 to treat ore from the mine.

At the Waihi plant, according to the annual report of the superintendent, E. G. Banks, work was mainly directed to crushing 622 tons of $16.74 ore with 92.1% extraction; treating 4807 tons of old tailing averaging $4.49 per ton; and cleaning-up valuable material about the plant.

The Victoria mill of 200 stamps and 11 tube-mills worked 300.66 days, an average of 123.23 stamps dropping, and crushing 184,146 short tons of dry ore through a 10-mesh screen. An average of 6.36 tube-mills worked, and the average duty of stamps was 4.97 tons per day. The ore assayed $8.24 gold, and 2.75 oz. silver per ton. Vanners saved 2325 tons of concentrate, assaying $145.40 gold and 37.25 oz. silver per ton. This was treated by tube-milling, air agitation, and filter-pressing with 96.7% extraction, at a cost of $6.36 per ton of concentrate, and 8.01c. per ton of ore treated. Amalgamation was discontinued in July 1913. The proportion of sand, slime, and concentrate treated from the ore was 27.84, 70.93, and 1.23% respectively. The total recovery from leaching, filtering, and concentrate was 90.7% of the value of the ore, against 89.7% in 1912, 89.3% in 1911, and 88.5% in 1910. Silver recovery was 80.1 per cent.

The clean-up and melting department treated 76,853 lb. of precipitate from the zinc boxes, yielding 535,544 oz. doré bullion. The refinery treated this, producing gold 999.8 and silver 996 fine. There was also sent abroad 29 tons of refractory residue, and 135,629 oz. copper-lead bullion. The assay department handled 9132 samples of air, ore, and bullion. Receipts from bullion were $1,613,000, of which $572,000 was profit, and $475,000 was paid in dividends. Transport of ore and treatment cost $1.93 per ton.

Timber Flumes

The V-shaped wooden flume is held to be superior to the box or square-sided form, because it requires less water and, on the average, less repairs than the other type, is better adapted to act as a slide on steep grades, and offers fewer chances for jams. The metal flume will come into wide use soon. For handling railroad cross-ties, cants, poles, cordwood, mining stulls, and the like, a flume with the sides of the 'V' 30 in. high is large enough. For handling logs, piling, long timber, or brailed sawed lumber, a height of from 40 to 60 in. is recommended. The best angle for the 'V' is put at 90°, according to Eugene S. Bruce of the Forest Service. Flume lines should be surveyed with enough care to insure evenness of grade. Grades should be kept below 15% wherever possible, and the best results are obtained with grades between 2 and 10%. Abrupt curvatures in a flume should be avoided, for they are likely to cause jams. Curves should rarely be permitted to exceed 20°. The longer the material to be handled in the flume, the less abrupt should the curvatures be. Telephones are recommended as adjuncts to the operation of a flume. By their use a serious break or jam can be reported immediately to the head of the flume to prevent further shipment of material. A flume recently built on Rochat creek, near St. Joe, Idaho, is cited as a good example of modern V-shaped flume construction. This flume, which is unusually large and built to handle heavy logs and long timbers, is said to have cost approximately $8000 per mile for the five miles, including the cost of constructing a wagon-road and telephone equipment. Other flumes cost from $2000 to $7500 per mile.

PERUVIAN TRAILS AND THE WORLD'S HIGHEST WAGON-ROAD, ELEVATION 17,000 FEET.

Ore Treatment at the Santo Domingo Mine, Peru

This property is 142 miles from Tirapata, 104 miles of which is over wagon-road and 39 miles of trail, and at an elevation of 6000 feet. The old mine of the Inca Mining Co. has produced a large quantity of gold in past years, and a new mill has recently been started, according to *The West Coast Leader*. The gold occurs free, in sulphides, and is very fine in the *llauca*, or clayey material, and the ore averages about $750 per ton. The Company's mining engineer, E. G. Davidson, decided that the all-sliming cyanide process was most suitable for the ores. The new mill is erected on the side of a steep hill, and is 150 ft. from the ore-car track to the solution tanks. A Dodge crusher breaks the ore to 1-in. size, which is further reduced through a 30-mesh screen by two Huntington mills. On account of clayey material, 30% of the ore will pass 300 mesh on being ground, so the mills crush 20 tons each per day. The pulp flows to a Dorr classifier, where it is joined by 80 tons per day of old $8 tailing, which receives a little preliminary treatment before reaching the classifier. From this machine the slime goes to Frue vanners, and the sand to a Chalmers & Williams tube-mill. All the slime is thickened and then agitated in two sets of three 15 by 35 to 38-ft. Pachuca tanks. Pulp is filtered by an Oliver machine, and precipitation is on zinc shaving. Photographs are used by courtesy of A. B. Maxwell, formerly of the Inca Mining Company.

OVER THE ANDES TO SANTO DOMINGO, AND TWO VIEWS OF THE CYANIDE PLANT.

Relative Natural and Commmercial Scarcity of the Metals

By EDWIN C. ECKEL

The present article attempts to summarize briefly the main facts regarding the relative scarcity of the different metals, in nature and in trade. Since the data employed in the discussion are necessarily inexact, the results cannot be considered final, but they seem to have a certain general interest which makes up for their lack of precision.

Commercial Abundance and Scarcity

As a basis for determining the present commercial abundance of the different metals, one may fairly use the statistics of world's metal production in 1910, as representing the output during the last year of widespread industrial activity. The total output of the commercial metal during this year, in metric tons, was as shown in the first column of the following table, the results in the last column having been computed as a convenient basis for comparison.

Metal.	Output, metric tons.	Commercial abundance, gold = 1.
Pig iron	65,300,000	92,000
Lead	1,139,700	1,600
Copper	836,900	1,180
Zinc	816,600	1,150
Tin	115,700	165
Aluminum	43,800	60
Nickel	24,500	35
Silver	7,437	10
Quicksilver	3,600	5
Gold	704	1

The output of the different metals varies from year to year, so that their relative commercial abundance is not definitely fixed; but the figures for the year taken as the basis may be considered typical of the present period of metal production.

Relative Natural Scarcity

For comparison with the results stated above, it will be of interest to put into convenient shape such data as are available concerning the actual relative abundance of the different metals in nature. Various geologists and chemists have made investigations along this line, and though from the nature of the case precise and accurate data cannot be secured, certain broad features as to relative abundance and scarcity are brought out sharply enough.

The following table contains the data available with respect to the natural or geological scarcity of most of the commercial metals. The figures quoted for zinc, lead, copper, and gold are estimates published by W. Lindgren in his recent work on ore deposits, and may be taken as representing the most authoritative statement upon the relative scarcity of the rarer commercial metals.

The percentages credited to aluminum, iron, nickel, and manganese are taken from the most recent work by F. W. Clarke, and are based upon the results of a very large number of analyses of sedimentary and igneous rocks, made in the laboratory of the United States Geological Survey. These analyses were compared, weighted, and averaged by Mr. Clarke; and the four figures quoted below may be accepted as being as close to the truth as we are likely to get in this matter. The figures for aluminum and iron, especially, are unlikely to be materially changed by any further analytical work. Those for manganese and nickel, owing to the fact that they are based upon a far smaller number of analytical determinations, are of course less definitely settled.

The first column of figures in the following table are those taken, as noted above, from Lindgren and Clarke. The results stated in the last column have been calculated, in order to bring out more sharply some of the comparative results.

Metal.	Percentage in earth's crust.	Relative abundance, gold = 1.
Aluminum	7.84	15,080,000
Iron	4.44	8,800,000
Manganese	0.08	160,000
Nickel	0.023	40,000
Copper	0.0075	15,000
Zinc	0.0040	8,000
Lead	0.0020	4,000
Silver	0.00001	20
Gold	0.0000005	1

Relations Between Natural and Commercial Scarcity

From the figures given in the two tables above, it is possible to draw some comparisons between the natural and commercial scarcity of the different industrial metals. Certain very marked disparities will appear immediately, and the extent and importance of these differences are sufficient to suggest that further investigation of the subject would be of interest. In the present place, however, it will not be possible to do more than call attention to their existence and general character.

It will be most satisfactory to confine attention to the more important commercial metals, omitting those whose place in the scale is less definitely fixed. This has been in the following table, where the six leading metals are compared in turn as regards estimated natural scarcity, actual tonnage produced annually, and average price per ton for the period under consideration. In each case gold is used as the basis for reference.

Metal.	Natural abundance.	Annual output.	Cheapness.
Gold	1	1	1
Silver	20	10	33
Lead	4,000	1,600	10,000
Zinc	8,000	1,150	5,000
Copper	15,000	1,180	2,600
Iron	8,800,000	92,000	40,000

It can be seen at once that natural scarcity has no very direct influence upon either the tonnage produced or the price of the metals covered by this table. Even allowing for wide differences in the commercial utility of the various metals, and for the great variation in the metallurgical and other difficulties involved in their preparation, there still remain wide disparities between the figures in the three columns above. These disparities are of such a type as to suggest that disproportionate efforts are expended in the search for certain metals, and in overcoming the mining and metallurgical difficulties encountered in placing them in form for commercial use. The most striking instance is that of gold, which is apparently produced in tonnages far larger than could be expected, while its relative commercial value is much lower than its natural scarcity would seem to justify. If the discrepancy were confined to gold, it might be assumed that the serious error lay in giving that metal a rank for natural scarcity which the facts did not justify. But comparisons farther down the line will show variations of equal moment, and other explanations must be sought.

Methods of Taking Mill-Head Samples

By LLOYD ROBEY

In modern cyanide practice it is generally found advisable to stamp and grind the ore in solution. While this method has decided advantages in determining the system of stamping, it has one very serious disadvantage. This is, it is practically impossible to take a sample from the battery discharge stream that will give a correct indication of the value of the ore entering the battery. The reason for this is found in the fact that gold and silver are dissolved by the solution during the stamping process. The attempt has often been made to take a sample by the use of an automatic sampler below the batteries, determining the percentage of solution and dried pulp in the sample, and then assaying the solution and the filtered and washed pulp separately. This is sometimes varied by an attempt to dry the final cut-down sample.

These methods present great and obvious difficulties. As the amount of solution is from five to ten times the amount of ore, any error in the solution assay is multiplied by that amount before this assay is applied as a correction to the pulp assay. The difficulty is further increased by the fact that the so-called barren solutions are never entirely barren, but contain some gold and silver from the precipitation process; and as the assay results of these solutions are also multiplied from five to ten times before being applied as a correction to the pulp assay, it follows that another solution assay is necessary to determine the amount of gold and silver entering the mortar with the solution. Besides this, in many plants the pulp is thickened before entering the agitators and the surplus solution is pumped to the battery supply-tank without precipitation, so that a solution already comparatively rich enters the mortar and meets the ore. It is not denied that in an experimental run where every factor is carefully watched, pulp and solution samples being taken under supervision and thoroughly checked, approximately accurate results may be obtained. But the skilled labor and the care and patience required to do this accurately as a part of the daily routine, the mill superintendent may not hope to obtain. His aim is rather to so simplify mill processes that even ignorance and carelessness will not vitiate his results. I made a fairly complete series of tests by this method, checking against head-samples taken by other means. The solution carried considerable gold and silver. The work of sampling and assaying was entrusted to a skilled American assayer, and native millmen. In no instance did the assays check or show any uniformity. Occasionally, after making the proper calculations, the astonishing result was reached that the ore carried a minus quantity of gold.

The method of drying a sample can never be accurate because the evaporating solution leaves a large percentage of the precipitate on the sides of the container. To scrape this off and mix it accurately with the pulp is out of the question. The operator, therefore, apparently finds himself reduced to one of three courses: To build a sampling plant, expensive both in first cost and operation; to eliminate head-samples altogether, deducing his extraction from his bullion account and tailing samples, dispensing with the check of theoretical against actual extraction; or, finally, to depend on some cheap and apparently inadequate method of hand sampling, taking the sample somewhere between the crusher and the stamps

The first method is often out of the question for small companies and is seldom advisable in other than custom mills if a satisfactory substitute can be found. In the second method the operator trusts to his vigilance and skill to prevent losses by leakage, millmen's mistakes, overflowing tanks, and stealing. Though he may be sure of himself, his confidence is not always shared by his superiors, especially when the heads are disappointingly low and the mine superintendent has a settled conviction that his ore runs higher than the mill reports show. The method has the added disadvantage that heads can only be known at clean-up time, and then only approximately on account of the ore still in course of treatment. Thus the miner has no check to enable him to supply a uniform grade of ore, and the mill superintendent has no data to enable him to make estimates of production for the information of the Company. The third method is often attempted, and frequently leads to much grief and tribulation. As a matter of fact the most of this

trouble is unnecessary. The millman who follows the simple plan outlined below will generally be able to place his trouble promptly and thereafter rest in peace.

The importance of taking a very large and definite quantity of the ore received for the first cut or primary sample in continuous non-custom mill-work has been greatly overestimated. Such a sample must be taken on shipments to custom smelters, mills, or samplers because each lot is paid for separately. But in an ordinary mill running full time the slight variations in the daily head-sample, due to taking a small cut or even taking one at irregular intervals, are compensating errors which will balance themselves and approximate the correct average in a very few days, providing that the cut, no matter how small or how seldom taken, is made in a correct manner, and also providing that the subsequent cutting down and assaying is correctly performed. If the ore is received from a bucket tram after crushing at the mine, every twentieth bucket may be dumped in a separate sample bin, thus giving an amply large sample. Otherwise, the sample may be taken occasionally by the battery helper from the lip of the feeder, using a wide shallow hand-scoop held just below the lip. In this case a small lined chute, leading to a sample bin under the ore-bins and back of the mortar blocks, is a great convenience. This may seem a very careless make-shift sample, but the operator will be surprised on testing this method to find how accurately these small samples will check in a month's run, providing only that they be fairly taken and exactly cut down.

If trouble has been encountered in checking samples the following procedure should be adopted: Take the original sample and cut it down by any good method to about 400 lb., cone and quarter this sample, and run each quarter separately through the entire remaining process to the final assay. It will probably be found that these assays vary widely. In the next day's sampling, repeat the operation but buck down about four times as much pulp and pass it through a finer mesh screen. With very difficult ores it may be necessary to buck down two or three pounds to pass a 150-mesh screen. If the trouble still continues, go back to the preceding step, passing an increased quantity of sample through the finishing rolls (say, to 20 mesh), and so on, working backward each day to the preceding step. As a general thing the trouble will be found long before the operator has worked back to the original sample. The four quarters should be cut down separately for several days until it is certain that they will check consistently, and then two of them may be dropped, but the other two should always be run. The point is that, in nearly every case where a serious discrepancy exists between the actual and so-called theoretical extraction, the trouble will be found (assuming that it does not exist in the actual mill work) not in the small quantity of the sample taken, nor in the unequal periods of sampling, but either in the lack of care in taking a fair cut, with too much or too little fine material, or more probably in the method in which the sample is handled in the laboratory. In my experience with a very difficult ore, averaging about 35 oz. silver and 0.3 oz. gold per ton, this investigation was made, and the four quarters failed to check by from 4 to 8 oz. After the laboratory procedure was revised, these quarters seldom failed to check within 0.5 oz. of silver. The moisture sample presents another troublesome problem, particularly with very wet ores. It is useless to weigh, sample, and assay the ore correctly if an error of from 1 to 3%, constant and always of the same side, be allowed to creep into the moisture account. The head-sample is useless for moisture determinations, because in standing for hours it loses moisture both by draining and evaporation. There is but one logical method for taking moisture samples, and that is by taking entire carloads or tram-bucket loads, which are weighed, dried, and re-weighed. This should be done on a number of cars at first, and checked occasionally afterward. By this method we substitute a compensating error, which tends toward a correct average, for an unbalanced and probably greater error. This point of taking all samples—head, tail, moisture, or others—in continuous mill work so that errors shall be of a compensating character, is of capital importance. The wise superintendent knows that he cannot depend on millmen, particularly natives, always to sample carefully in the long hours of the night shift. But if by careful study he can arrange his sampling so as to eliminate the unbalanced error, he may be sure that his compensating errors will never affect his bullion check to a noticeable extent.

COAL PRODUCTION of France in 1913 was 40,129,410 metric tons, against 40,394,177 tons in 1912. The output of lignite was 792,793 tons, an increase of 41,792 tons. Imports were 11,257,431 tons from Great Britain, 3,659,669 tons from Belgium, and 3,482,287 tons from Germany. There was also imported 3,070,036 tons of coke, and 1,086,045 tons of briquettes. Mining property of France covered 1,383,785 acres in 1913. Iron-ore production was 21,714,000 tons, against 19,160,000 tons in 1912; also 1,681,992 tons came from Algeria and Tunis. Output of steel was 4,635,166 tons. There are 103,000 men employed in the iron indnstry.

COAL was mined in Oklahoma in 1913 to the amount of 4,165,770 short tons, valued at $8,542,748, both record-breaking totals for the state, according to figures compiled by E. W. Parker, of the U. S. Geological Survey, in coöperation with the Oklahoma Geological Survey. Oklahoma, more than any other of the coal-producing states in the Mississippi Valley and the Rocky Mountain region, was benefited by the labor troubles in Colorado, as is shown by the increase in production over 1912, amounting to 490,352 tons, or 13.34%. The value of the product increased $675,417, or 8.6%. There were 9044 men employed.

A THIRD blast-furnace is now treating copper ore at Katanga, Central Africa.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Rock Nomenclature in New Mining Districts

The Editor:

Sir—The article in the *Mining and Scientific Press* of April 25, 1914, on 'Geology of the Kalgoorlie Goldfield,' discussing at length its rock nomenclature, emphasizes again the difficulty of accurate nomenclature in regions of complex metamorphosed rocks, altered by subsequent mineralization. It also suggests another point of practical importance to the mining engineer and geologist, the inadvisability in a new district or where detailed geological work has not been done, of depending on petrographic names in describing surface and underground exposures, diamond-drill cores, etc., until the general characteristics, relations, and history of the formations have been determined by field and microscopic work.

Mr. Larcombe says: "I think all geologists are agreed upon the impossibility of different authorities giving the same name to highly altered rocks in the Archean complex." How much more then are young mining engineers and geologists, whose ideas of petrographical nomenclature are not so clearly crystallized, but who nevertheless have to do most of the routine work of geological note-taking, going to differ in their use of felsite, greenstone, metamorphosed tuff, and similar terms. The result is often that the notes of the man in the field are of little use to the next one until he succeeds in working out the former's conception of the petrographic names used and can in the field visualize what he actually saw when he wrote "cross-cut No. 3 N. at 30 ft. from drift cut contact of felsite and quartz andesite, the latter much altered, dipping * * *" Similarly reports and geological literature based on extensive microscopic work may be less applicable to future economic work through the use of petrographic names and descriptions drawn from examinations of thin sections, but lacking in sufficient megascopic description of hand specimens. The gold, silver, lead, and zinc deposits of the Altai in Siberia afford an excellent illustration. A mass of Russian reports and maps are available, but are of less practical use because they attempet to name rocks in part too metamorphosed and altered to classify petrographically without long study of thin sections, though frequently possessing sufficient physical differences in color, hardness, and structure for field identification and correlation.

I have lately, therefore, been trying to follow the rule in geological department work that to begin with all descriptions of cores, etc., must be as complete megascopically as possible, instead of seeking too early for names which involve more knowlege of the geological history and relations and more microscopic evidence than is usually available. Taking examples from recent notes, "very hard and dense gray rock with conchoidal fracture and no visible grain or phenocrysts" is preferable to 'felsite' or 'hornsite' and "rock as a whole unusually bright green in color (epidote?), mottled with white (altered feldspars?), and characterized by a minor amount of very dark greenish black chlorite" preferable to "greenstone probably metamorphosed diabase."

Of course, it is not necessary to repeat long descriptions every time one notes obviously the same rock underground; a name is soon found for every prominent type, but every variation from each type of which the full megascopic description is made should also be described the same way and not recorded in such terms as 'altered greenstone' which may carry a different significance to another man or the same man in the field again a month later. Furthermore, it should not be forgotten that even after the true character of the rocks has been established by microscopic work, these megascopic descriptions may be useful in correlating rocks cut by new drill holes; work which cannot always wait for thin-section examination.

Summarized, of course, this is only further emphasis on one phase of the necessity of detail in geological note-taking and on the danger of letting deduction run too far ahead of observation.

C. T. Brodrick.

Barnaul, Siberia, June 10.

[The difficulty of fitting the inexact knowledge of the field to a possibly overdetailed and very complex system of petrographical nomenclature is one of long standing. In a sense it is but one phase of the general problem of getting people to use words for the same meaning; a problem incapable of complete solution. In the case of rock names, the difficulty is especially keen because the methods of field and laboratory are so different as to require really two sets of names, and no agreement has been reached as to either set. The only safe rule to follow is the one our correspondent has suggested; namely, the personal one of making no pretense at any time to more exact knowledge than the note-taker really has. This coupled with clear descriptions of what is meant by any of the terms used is the best preventive of misunderstandings. Rocks may be numbered, lettered, or named temporarily after favorites of the footlights, provided that the notes include the description

of the essential characters of each rock type differentiated.—Editor.]

The Rand Banket*

Reply by Mr. Horwood to Henry H. Knox and to J. S. Hook's Criticisms.

I am much obliged to both Mr. Knox and Mr. Hook for pointing out that I misinterpreted C. R. Van Hise's rule for the change in volume for metasomatic replacement. I admit that I had done so,† and am glad to have this opportunity of expressing my regret to Mr. Van Hise for this mistake and my consequent criticisms on his work. As Mr. Knox and Mr. Hook point out, in the metasomatic interchanges described by me, the volume of the pyrite is to that of the replaced quartz approximately what it should be according to their interpretation of this formula. The figures I used for the molecular weights and specific gravities indicate that these volumes should be as 1.07 is to 1, but, as Mr. Knox points out, if these specific gravities, as might easily be the case, were 5.2 and 2.6, then the pyrite would occupy a slightly smaller space, which is more in accord with my observations.

Reply to S. J. Lett's Criticisms

Mr. Lett, in his discussion dated October 26, 1913, states that he found a piece of vein quartz containing pyrite in a Cretaceous conglomerate. I fail to see what bearing this has in relation to the pyrite replacements of the Rand banket. There may be pyrite in some of the quartz pebbles of these bankets which was present in the quartz long anterior to the formation of the banket; and in my paper, I made this perfectly clear in footnote 132 in Part III (cont'd). Mr. Lett maintains that the solubility of iron pyrite is no argument against the presence today of true pebbles of pyrite in the Rand banket. I would remind him that in his second contribution to the discussion on my paper, dated January 15, 1914, he speaks of the matrix of the banket as "a porous medium"; and as the cementation and induration of the banket probably took place at a fairly late period in its history there was plenty of time for the complete dissolution of such solution pebbles. Mr. Lett admits that he had at the time only received the first installment of my paper. In footnote 187 in Part IV, I stated that "It is quite possible that there may be a small proportion of pyrite and gold of detrital origin in the banket; but, if so, it is admittedly unimportant in discussing the genesis of the pyrite and gold." In some of the succeeding parts to the one Mr. Lett is criticising, I demonstrated the secondary origin of the pyrite.

Mr. Lett hoped that I would give an analysis of one of the typical dikes that occur in the mines of the Rand. In appendix No. 2 at the end of my paper there are analyses of two of these basic dikes.

As regards his further criticisms, dated January 15, 1914, I have read the paper by Mr. Todd to which he alludes. There has been no straining by me 'after a more complex origin' for concretions than that given by Mr. Todd. In the introductory portion of Mr. Todd's article he disclaimed intimate acquaintance with the chemical aspect of the subject. Mr. Todd explained the growth of concretions as due to particles gathered together toward a centre so as to produce growth regularly and steadily from the centre outward, and he termed these accretions, and said that they may sometimes have radiate structure that may be due to development of a modified crystalline structure. While admitting that a cracked interior may sometimes originate owing to internal shrinkage, he himself holds the opinion that such an interior is in general due to expansion of the outer portion. As explained in my paper, the microscope and other evidence clearly shows that some of the pyrite 'pebbles' or replacements in the Rand banket occur as metasomatic pseudomorphs; that the new mineral had to make room for itself by solution of the host mineral; and, that the original internal structure of the replaced mineral has sometimes been faithfully preserved.

Referring to my summary of Parts I and II, Mr. Lett says that I have forgotten the rejection by Mr. Lindgren of the molecule for molecule idea. I fail to see how he arrived at this conclusion, since I stated that in these metasomatic replacements the interchange had taken place by equal, or approximately equal, volumes; and that in such cases the change is usually considered to be molecular, but if so, it must be governed by some law of multiple proportion, because molecules of different substances vary in size so that if the exchange were molecular, equal volumes before and after would be the exception and not the rule. Later on in Part III (cont'd) I said that Mr. Lindgren in dealing with metasomatism considers that the reaction does not take place molecule for molecule, although he thinks it is molecular, or at least sub-microscopic.

At the beginning of Part IV of my paper, I pointed out that the examination of thin sections under the microscope showed that the commencement of growth of the concretionary pyrite pebbles was started by a minute amount of pyrite being precipitated, either directly from solution or by replacement of silica or silicates, or by both of these means. Thus a centre of growth was created around which pyrite continued to be precipitated, and that the rounded shape of the replacements was explained by fairly uniform growth around such centres. Further, that the microscopic investigation showed that there were generally several centres of growth for each 'pebble,' and I fully explained the final rounding of several such masses that had coalesced.

*[In this and subsequent issues Mr. Horwood will reply in detail to his various critics. His original articles and the discussion are to be reprinted in the form of a book, at which time various typographical errors that crept into the material as printed will be corrected.—Editor.]

†This will be rectified when my series of articles are published in book form.

As regards the selection of particular pebbles for replacement, I pointed out in Part III (cont'd) that the angular, indurated, slaty quartzite pebbles were more readily replaced by pyrite than pure quartz pebbles, and I dealt with the preference shown by the pyrite for replacing aluminum silicates and instanced, as pointed out by Mr. Lindgren, the frequent development by replacement of cubes of pyrite in shale; and also its frequent development in fine grained compact argillites after the hardening, and metasomatism of the rock at a time when it was exposed to mineralizing solutions that were producing ore deposits in adjacent fissures.

Mr. Lett suggests that the carbon was probably produced under pressure and at considerable temperature. He states that he has read my paper 'The Mode of Occurrence and Genesis of the Carbon in the Rand Bankets,' and that there I showed its origin to be attributed to magmatic vapors or solutions derived from neighboring basic dikes before their final solidification. This naturally implies such conditions.

I remarked that J. P. Iddings had pointed out that in the case of a crystal surrounded by a dissolving liquid, its angles and edges will be the parts most rapidly dissolved, resulting in a rounding of its shape. Mr. Lett criticises me for applying similar reasoning to the obliteration of rough outlines in the formation of these pyrite bodies. I can only conclude that Mr. Lett cannot have read this portion of my paper carefully since he bases his remarks on Mr. Iddings' statement that it does not follow "that curved, or rounded, surfaces develop only through solution of plane-faced crystals." On the same page and just before my reference to Mr. Iddings, I showed that the rounded shape is also largely due to the following factors: to fairly uniform growth around a centre; and in cases where two or more such bodies coalesced the combined surfaces would be exposed to modifying influences, due to continually renewed portions of active solutions, consequently any roughness of outline would tend to be destroyed, especially since any of the surrounding quartz embaying the surface of any such pyrite body would be gradually replaced by pyrite, as the whole process indicates that the already precipitated pyrite acted as a precipitating agent for that still in solution and that under the conditions that then obtained, the solutions had a greater chemical affinity for the silica than for the pyrite. Further, I pointed out that any roughness of outline would have presented greater frictional resistance, and since solution is most active at points of greatest pressure, any unevenness of surface would be toned down.

I showed that the black coloration of certain quartz pebbles was due to minute traces of chromium and manganese, and Mr. Lett argues that gold is more volatile than chromium and therefore a marked increase of the latter would mean diminution of the former, as it would have traveled further from its ultimate source; this reasoning appears to me far-fetched. The amount of chromium necessary to produce coloring effect is so minute that the amount present could hardly be gaged by this means with any degree of accuracy at all.

Mr. Lett refers to my suggestion that the pyrite and gold may have been present in the mineralizers as a eutectic mixture and says, if so, one would expect to find a fixed ratio between the gold and pyrite in the banket. I do not agree with him, and in Part IV of my paper, I pointed out that if such a mixture existed the pyrite present in excess of the eutectic ratio would have been precipitated first, until the eutectic point was reached when the gold and pyrite would have come down together. Thus there would always be pyrite present in excess of the eutectic ratio. Mr. Lett apparently suggests the possibility of an area in vertical range where gold and pyrite in eutectic proportions alone might be deposited: I think this is highly improbable, and there is certainly no evidence of such area on the Rand.

As regards alternating poor and rich zones, I have already dealt with this subject at considerable length in Part V of my paper, and illustrated it by a series of curves, and I would especially refer Mr. Lett to Fig. 23, 24, 25, and 26.

Small Type

The Editor:

Sir—In an editorial of May 9 you ask the indulgence of your readers for presenting the decision in a recent lawsuit in small type. This, to my mind, is an exceedingly valuable feature and I wish it were followed in all technical journals. Small space and weight are points of great importance to engineers, who, as most of us do, extract from the technical press, and especially so to those who travel much on expensive stage and railroad lines. The precis of technology given in *The Mining Magazine* of London is a model of compactness. Many a good article has found its way into the waste basket which, if it weighed half as much, would have been placed on file.

'Rolling Stone.'

Globe, Arizona, May 26.

Ore

The Editor:

Sir—Your issue of March 14, containing T. A. Rickard's reply to my criticism of his definition of ore, published in the January 24 number, has only just reached me.

I wish to express my appreciation of the tone and tenor of Mr. Rickard's reply. I accept gladly and with humility his correction in regard to the split verb. I regret my lapse. The lance of a watchful opponent has found an entrance into an armor that is all too vulnerable; nevertheless, I hope that admission to the circle of the best families will not be denied me when, as at this present juncture, I place a humble and hesitating foot on the literary threshold.

G. Aubrey Gow.

Wellington, New Zealand.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

OIL PRODUCED in the British Empire amounts to only 2.06% of the world's total.

ELECTRIC POWER in Germany is frequently sold at $19.04 per horse-power year.

AMALGAMATION TREATMENT is responsible for 70% of the output of gold from Rhodesia.

ALLOYS OF GOLD AND SILVER show only a slight reduction in melting point below that of pure gold as long as the silver is not in excess of the gold.

FINE GOLD, according to Rose, may be drawn into wire of such thickness that 1 oz. will cover fifty miles. Gold leaf can be made one-three hundred thousandths of an inch in thickness.

CARBON BISULPHIDE is used as a solvent to extract the remaining oil from pulp and stones of olives after the 'expressing' process. The product obtained is known to the trade as sulphur oil.

PRESSURES up to nearly 300,000 lb. per square inch have been obtained in the physical laboratory at Harvard University. With reasonable accuracy these were measured up to 175,000 pounds.

TUBE-MILL FEED can seldom be arranged so that the mill works under absolutely ideal conditions. A certain amount of elasticity of operation is available with this machine, and pebble volume can be varied to conform with a slightly higher or lower feed than may have originally been intended.

GRAPHITE is mined, and is also manufactured by electric furnaces. The percentages of the world's production of graphite used for various purposes have been estimated as follows: crucibles, 55%; stove polish, 15%; foundry facings, 10%; lead pencils, 5%; paint, 5%; lubricants, 5%; all other uses, 5 per cent.

LEAD POISONING is rare in regular foundry work, or where alloys containing under 8% lead are melted and worked. Lead enters the body through the nose and mouth, and leads to indigestion, lead colic, diseases of the heart, blood vessels, and kidneys, and to paralysis of the hands, known as 'wrist-drop'. The poison acts slowly and insidiously.

A SILVER-COPPER ALLOY of homogeneous composition may be made when the proportion of silver amounts to about 72%. With a variation in silver percentage above or below this amount a 'segregation' is liable to take place on cooling which will result in the outside of the cast being poorer or richer than the average fineness of the alloy.

COAL GAS for lighting and power, manufactured by the Widnes corporation or municipality in England, is sold for 24c. per 1000 cu. ft. to users of less than 3,000,000 cu. ft. per year, 20c. for over that quantity, and 16c. for all power purposes. New retorts have resulted in gas being made 20 to 27% cheaper than that of the nearest competitor, the Sheffield Gas Company.

HYDROGEN PRODUCED as a by-product of the electrolysis of the alkaline chlorides in Germany, amounts to 10,000,000 cubic metres per year, equal to 896 metric tons. Also about a similar quantity liberated in the electrolytic production of oxygen for commercial purposes, from solution of alkaline hydronides. Hydrogen is sold at Griesheim and Bitterfeld for 12c. per pound.

ALKALINITY ESTIMATIONS, involving the calculation of the exact amount of pure lime to be added to an ore to counteract acidity, are of little practical use because the acidity of the ore and the alkalinity of commercial lime are both liable to fluctuate daily. A better plan is to add sufficient lime to the ore so that daily titrations of plant water or solution demonstrate the presence of a definite percentage of alkali. In buying lime for neutralizing purposes the sale should be effected on the actual percentage of CaO present. Powdered quicklime should be rejected, as it invariably leads to a loss on the part of the buyer, due to the difficulty of estimating lime content; and also on account of the wide variation in moisture content.

COAL PRODUCED in the United States is nearly all mined by the room-and-pillar system, or some modification of it. The longwall method of mining, so well adapted to many thin seams, is neither understood nor appreciated in this country. The only field where longwall mining produces any considerable tonnage is in northern Illinois in Will, Woodford, Putnam, Marshall, La Salle, Grundy, and Bureau counties, where the annual output is over 5,000,000 tons, or 9% of the state's total coal yield. The production of this tonnage is attended by 24.5% of the non-fatal accidents in coal mines in the state. The per capita production per employee is only 2.1 tons as compared with 4.5 tons for the state as a whole. The longwall method of mining makes an almost complete extraction of the coal in the bed, and produces about 15% more lump coal over 1¼ in. than is produced in Illinois room-and-pillar mines.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

UNIONS AT BUTTE.—THE RECENT CLASH AND CAUSES OF THE OUTBREAK.—FURTHER TROUBLE LIKELY.—EFFECT ON BUSINESS.—GENERAL MINING ACTIVITY.—OIL PROSPECTING.

Butte is now experiencing the unusual situation of having two miners' unions competing in the same field. The new and recently formed organization is called the Butte Mine Workers' Union; the old organization is called Butte Miners' Union Number One, Western Federation of Miners. The events which have led up to this anomalous situation are briefly as follows: On June 11 the miners in two of the mines refused to go to work under conditions requiring them to show the old union cards. On June 13, Miners' Union Day, only a few score men tried to take part in the miners' parade, while a large crowd of disaffected ones gathered on the streets, jeering the paraders, and finally attacked them in person. The attackers then rushed for the Miners' Union Hall, broke into it, and destroyed records, furniture, and everything breakable, throwing the refuse out of the windows. When the acting mayor of the city tried to prevent this destruction by making a speech to the men, some one pushed him out of a second-story window to the stone pavement below, injuring him seriously. That night a crowd took possession of the miners' union safe, carried it to a point without the city, blasted it open, and carried off its contents of money, papers and records. Within the next few days the disaffected miners formed the Mine Workers' Union and began to enroll members.

These disturbances brought C. H. Moyer, president of the Western Federation of Miners, to Butte. On June 23 he attempted to hold a meeting of the old union in the hall, which had been temporarily repaired for that purpose. A large crowd gathered outside the building during the meeting, jeering at those who entered. Finally some one from within the hall shot and seriously wounded a miner who was just entering the building. This was the signal for a volley of shots from both sides, with the result that an innocent bystander across the street from the hall was shot and killed. The shooting so angered the crowd without that, in spite of protests from the leaders of the new union, dynamite was secured and the old union building was blasted again and again during the night until only a tangled mass of ruins remained. The city and county authorities claimed to be unable to prevent these acts of violence, stating that armed interference on their part would result in a greatly increased loss of life and probably uncontrollable riot. In fact, when the mob besieged the city jail and demanded the release of two of their number who had been arrested, the authorities were not long in complying.

In the foregoing statement an attempt has been made to record the facts impartially. Now, as to the cause which produced these events, the two sides of the case offer divergent evidence. The adherents of the old union, who are decidedly in the minority, aver that the rebellion was brought about by a radical element of the union who had not been paying their dues and who were anxious to have the Butte miners affiliate with the I. W. W. or some similar anarchistic organization. The sponsors for the new union claim, on the contrary, that they are not interested in the I. W. W. or any other outside organization; that their rebellion was necessitated by a long series of abuses in the old organization which they had been unable to correct by peaceful means. They say that the old union has been run in recent years in a manner not to the interests of the miners, that excessive dues and assessments have been levied for the support of unsuccessful strikes in other districts, that the funds so collected have been in part misappropriated, and that an inside clique has controlled the affairs of the union to the exclusion of the rank and file.

Just at present all is apparently quiet in Butte, but those who claim to know, believe that more troubles are yet to come. Moyer and his supporters are marshaling their forces apparently with the purpose of deciding whether they are strong enough to try to oust the new union. Their method of trying this will probably be to send representatives to the mines and demand the old union cards of the men who go down to work. The immediate objection to this method is the difficulty of securing lieutenants who would try to carry

RESULT OF A DISPUTE BETWEEN LABOR UNIONS AT BUTTE.

out such a plan. It would undoubtedly be a foolhardy thing for any man or group of men to appear at the mines now for that purpose. An alternative would be for the Western Federation to persuade the hoisting engineers, smeltermen, and other allies to strike if the mine continued to employ the so-called scab labor.

The mining companies have been able so far to keep out of the trouble, and the mines continue to work as usual; but the situation is admittedly tense, and has already reflected adversely on business conditions in Butte. Real estate men are especially 'blue,' and the mine promoters claim that investors have been so frightened by the threatening conditions that no money can be raised at present for Butte ventures.

Smelter superintendents and others in a position to know of ore shipped and smelted, state that there is a noticeably increased activity among the smaller operators throughout the mining districts of the state. No one property can be credited with any great developments or greatly increased production, but the general outlook is encouraging, with a good'y number of small shippers active.

The success which has been had recently in the fields about Calgary has aroused eastern Montana anew to prospect further for oil. Various attempts have been made in times past to find commercial amounts of petroleum in Montana, but so far without success. A well is now being drilled at Great Falls, and preparations are under way for the drilling of several wells near the Canadian boundary in the region of the Sweet Grass hills. A seepage has been found in the latter place, and the conditions appear favorable for oil concentration. A broad anticline runs north and south through this region for several hundred miles. This anticline has been locally 'domed' by igneous intrusions in the Sweet Grass hills, and in the region of this doming the wells are to be sunk. Butte capital is interested in one of the companies.

NEW YORK

Discussion of Business Situation.—Chile Copper Co.'s Finances.—Braden Mine.—Utah Copper Mine.—Stewart Mining Co.'s Affairs.—Nipissing and La Rose.—Tombstone, Arizona.

The undertone in the New York market has been largely lost to sense of sight, sound, or touch during the past week, while the deplorable consequences of unsound financing of the railroads has claimed the attention of federal authorities and banking interests alike. The present time is evidently to be marked as one of those eras of reorganization that are apparently bound to follow periods of constructive activity in this country. American financiers have hitherto found justification for undue expansion in the ability of the country to grow up to anything within the compass of reasonable expectation. The coming generation of financiers must learn to face changed and changing conditions. The press of population in congested centres is no longer easily and automatically relieved. There are no longer new empires to be developed on the old basis of vast subsidies to pioneer railroad builders. We have much work to be done, more work than ever; never was there so great need for that class of labor that can win an independence from the soil, but we have yet to overcome the traditions of our country; to learn that greater effort is necessary to secure smaller rewards; that there is no longer unearned increment to accrue to everyone as in earlier years. Crystallization of conditions, in as far as it has progressed, has in nearly all lines, except those of agriculture, worked toward the elimination of the individual as a factor. This has been true in mining as in other industries. The larger part of our present condition of unrest and stress and struggle is the attempt of the individual to win back his place in the work of the world. Through the dust of the present struggle between financial and political powers can be seen a turn in steel; mills are being started up, those that have been running one shift are working double shift, and plates, shapes, and bars are being advanced in price. Whether copper is to follow cannot as yet be foretold. Nearly every copper authority expresses the opinion that the world's uses for the metal have so grown as to make improbable, if not impossible, the accumulation of stocks of metal large enough to threaten price stability. The copper producers themselves are, apparently, assured of their position, and such price concessions as are made are due to general business conditions and not to anything inherent in the copper situation. At the moment, the metal market is flat with prices around 13¾c. per pound. The one element in copper production that works against true economics lies in the necessity of keeping the huge units in operation, the tremendous organizations together, and consequent price reductions to a level that is too close to production cost.

The management of the Chile Copper Co. has distributed about $2,000,000 of the convertible bonds remaining in the Company's treasury. The Chuquicamata was capitalized on a rather odd basis, the authorized stock issued being $110,000,000, of which $15,000,000 was retained in the treasury against a convertible bond issue of like amount, the $95,000,000 of stock was stated to have been taken by the Guggenheims, who also took one-third of the $15,000,000 of convertible, $5,000,000 was distributed to the public at the time of the organization, and now $2,000,000 more has been subscribed, leaving about $3,000,000 in reserve. The marked success of the Guggenheim organization is shown in the fact that the flotation of the Chuquicamata has been made without any open appeal to the public. There has been no market flotation of stocks or bonds, and it must be recognized as something of a triumph to be able to get together a following strong enough to finance privately a new mining property in a far country to the tune of $15,000,000.

Braden, now the second in importance of the Guggenheim propositions in Chile, makes haste slowly. A recent snowslide was attended unfortunately by a considerable number of fatalities among the native laborers. The enlargement of the present mill and later additions to mill capacity to where there can be handled 10,000 tons of ore per day is the present program for Braden. There are some other copper deposits in Chile that are being examined in behalf of the Guggenheims, which are said to be quite promising.

In the meantime, the magnitude of operations at the properties in this country controlled by this group continues to increase. Time was when 100,000,000 lb. of copper per year was looked upon as a barely possible achievement for Utah—now further expansions are being discussed. The steam-shovel department is getting to a point where it can deliver ore in larger quantities, and the only obstacle in the way of increased output would be bringing up certain sections of the mills, mostly a matter of addition to vanner-table and fine-crushing departments.

The fight for control of the Stewart Mining Co. which has been going on between F. A. Heinze and the Assets Realization Co., the latter faction headed by John W. McKinnon, has resulted in a receivership for all of the assets of the Company in the state of New York. A like fight is being waged in the courts of Idaho for the control of the mining property, though the McKinnon people are endeavoring to have the cause transferred to the United States courts. Recently, shareholders were surprised to receive dividend checks drawn on Saratoga (New York) banks. Evidently this was a part of the court fight, and the shift was made to avoid threatened injunction proceedings. Heinze's loans on Ohio Copper bonds are still in the 'Street'; some of these are also mixed up in injunction proceedings. While it would be hard to find many sympathizers for Heinze in Wall Street, it does seem something of a shame that one who could do as much as Heinze could do, should not have been able at the same time to spend his energy in the right direction.

There has been recently some little talk of declining production and decreasing ore reserves in the Nipissing at Cobalt. President E. P. Earle, who has just returned to New York from the camp, says that conditions at the mine are excellent; that net earnings for the first six months were $900,000 (dividend requirements are $600,000); that ore reserves were increased to such an extent as to justify the positive prediction that earnings would not decline during the latter half of the current year. Nipissing, like other properties in Cobalt, has been holding its own by dint of increased efficiency in milling operations. La Rose, which has always been coupled with Nipissing, as one of the leading producers of the Camp, is not in so good stead. A report has just been mailed to the shareholders by the secretary of the Company stating that unless operations during the next 90 days showed a very considerable improvement, the Company would distribute its surplus, which now amounts to $1,547,420, suspend operations, and surrender its charter.

Not everyone who attempts to keep up with the mining news concerning Utah Copper and the camp of Bingham realizes that Bingham cañon turns out anything besides copper. As a matter of fact, the output of lead is very important, amounting to no less than 75,000,000 lb. per year.

The story of some of the big mines and their vicissitudes, their triumphs, their eclipses, and their occasionally surprising rejuvenation make up some of the most interesting chapters of reminiscence. The old tales of the camp of Tombstone, Arizona, and its bonanza days will be worth digging out of pioneer history now because of the possibility of the renewal of production, now that the Phelps-Dodge company has acquired the Tombstone property. The Development Company of America, which some years ago undertook the exploitation of several large properties in the Southwest, secured control of the Tombstone mine and organized as its leading subsidiary the Tombstone Consolidated Mines Co., Ltd. This particular enterprise was to be the backbone of the whole organization. A securities-selling campaign landed the stocks and bonds in many hands all over the country, as discussed in the *Press* of June 13 and 27. The difficulty, as is well known, was the handling of a surprisingly heavy flow of water found in the mine.

CALGARY, ALBERTA

GASOLINE PRODUCTION FROM WET GAS, AND PLANTS CONTEMPLATED.—NEW HIGH-GRADE OIL DISCOVERIES.—DRILLING OPERATIONS.

The most important of recent developments in connection with the Calgary oilfield is the success of the tests made at the Dingman well in distilling gasoline from the flow of wet gas. A testing plant was put in and worked intermittently for two days, resulting in an extraction of gasoline somewhat in excess of the analysis which showed about 1.5 gal. per 1000 cu. ft. If this is borne out in practical working, it will make possible the economic development of large areas not within the oil zone, as flows of wet gas are often met with in the course of comparatively shallow drilling, where the oil lies too deep to be reached. At 700 ft., Dingman well No. 2 is giving 1,000,000 cu. ft. of wet gas per day, and should the results of further development justify it, the installation of a $50,000 condensing plant for the production of gasoline is contemplated.

A small quantity of oil has been taken from the well of the Southern Alberta. The analysis shows a light oil of specific gravity about 45° and a smaller quantity of heavier brown oil. Though not great, the find is regarded as decidedly encouraging.

Drilling is progressing rapidly in many of the wells. Contracts for the drilling of 30 new wells have been closed with the Janse Drilling Co., which will be proceeded with as soon as the equipment can be brought to the ground. The wells now contracted for include six for the Alberta Associated Oils, Ltd., three for the Western Canada, and from two to five each for the following: Livingston Fork Syndicate, Stokes-Stephens, Fidelity, Sarcee, Huron-Bruce, Mr. Stephen, Lion, Peerless, Noehren-Mannix, and Western Petroleum. Wireless communication has been established between the oilfields and Calgary. Field stations have been installed at about a dozen of the leading properties in charge of government-licensed operators. It is hoped that this will have a tendency to prevent the spreading of false reports regarding oil finds, and to insure a reliable news service. Some excitement over prospective oil discoveries in the neighborhood of Nakamun, in the Edmonton district, has been occasioned by the visit to that field of Julius Fried, of California, a prominent and wealthy operator, who has secured large holdings in Nakamun. A large amount of land in that vicinity has been taken up by local capitalists, and drilling will shortly be undertaken.

WASHINGTON, D. C.

OIL AND GAS LAND LEGISLATION IMPORTANT TO CALIFORNIA INTERESTS.—GOVERNMENT DEPARTMENTS NOT TO SEND OFFICIALS TO MEETINGS OF SOCIETIES.

The House of Representatives has under consideration the bill already passed by the Senate protecting locators of oil and gas lands in California. The bill especially considered, and which is hoped soon to pass, provides temporary relief pending final settlement of various suits. There has been some objection on the part of the Navy Department and the Department of Justice. As a result of conferences, an amendment to the bill has been agreed upon. The substance of it is that the royalties that come from the oil in the so-called 'naval reserve' lands are to be set aside for the Navy Department. There are 7600 acres in the two reserves, created under the Pickett act. Approximately half of that land—30,800 acres—is patented to the Southern Pacific railroad; 7500 acres of the other half is claimed by locators. The unentered and unclaimed lands amount to 29,650 acres, but there are some locations in that area which have not been applied for, so that there remain but 21,000 acres not in litigation. The proposed legislation is important to California, where a large number of locations and applications are under investigation or involved under proceedings which challenge the validity of the locations or the regularity of the applications presented. Many oil and gas wells are in actual operation upon these and adjacent lands, and by reason of the investigations of the Department of Justice and certain suits instituted by the United States to enjoin parties from removing oil from the lands, the operators are unable to dispose of the oil or gas pending adjudication. Failure to operate the wells continuously may result in the diminution or the destruction of the gas or oil through the introduction of water or by reason of the draining off of the oil or gas deposits from under the lands involved through wells sunk and in operation upon adjacent patented land. The legislation does not provide a method for disposing of the lands or deposits after final adjudication of the cases. Opposition to an amendment developed in the House, and pending a settlement the bill was left on the calendar without prejudice. There is before Congress and now on the calendar a general bill for the leasing of lands containing deposits of oil, gas, and certain other minerals, which will prevent future difficulties, and it is believed that the necessity for passing the temporary measure outlined only emphasizes the need and importance of general legislation.

Congress has done away with the liberty of bureaus not in the Department of Agriculture of sending experts to appear before public meetings and associations. It has been the custom to send experts, and even to pay their dues to belong to such bodies, wherever this was thought expedient. Congress has never liked this expenditure, and has positively forbidden it except in the case of the Department of Agriculture, where there are many bureaus conducting experimentation for the benefit of farmers. Congress has a profound regard for the Department of Agriculture, which teems with experts of all sorts who go out to the farmers, the Government paying all expenses. Other bureaus have not this popular support and hence they have been cut off. In consequence, hereafter the meeting of mining associations will not be attended as heretofore by government experts, either to learn for the government or to impart information to the miners. The Bureau of Mines regards this prohibition with great sorrow, for it is hard hit in its work of disseminating mining knowledge through direct personal touch.

The conference report on Sundry Civil Bill, carrying appropriations for the Geological Survey, Bureau of Mines, and many other bureaus, has now been accepted. The bill carries few increases in appropriations.

LONDON

ST. JOHN DEL REY AND OURO PRETO COMPANIES' OPERATIONS IN BRAZIL; THE FORMER A GREAT SUCCESS, THE LATTER UNPROFITABLE AT PRESENT.

The two English-owned gold mines in Brazil present considerable variation in fortune. Whereas the Morro Velho mine, owned by the St. John del Rey company, has mined to 5226 ft. vertically, and has had continuous success for ten years, the Passagem mine, belonging to the Ouro Preto company, has recently been in a poor zone and has had to raise further working capital. The St. John del Rey company has been in existence for 83 years, and the last annual report, covered in the *Press* of July 4, shows that £10,000 was paid in dividend on the 10% preference shares and £54,627 was paid on the ordinary shares, being at the rate of 10%. The labor situation has greatly improved of late, and the full complement of men is now employed; this is due to the construction of several railways and public works having been suspended. In regard to development at the mine, the 'G' shaft has been sunk 223 ft. below No. 18 or 5226-ft. level. It is to be continued to 5526 ft. and then a drift will be started to intersect the lode. George Chalmers, who reopened the mine in 1884, continues to direct the fortunes of this remarkable mine.

The other company, the Ouro Preto, owning the Passagem mine, is under the guidance of John Taylor & Sons, and it has been far from successful. It was formed in 1884, and reconstructed in 1893; now comes another writing down of old shares, and another subscription of new capital. Dividends on a small scale have been paid occasionally, but on the whole the venture must be classed as unprofitable. The report for the year 1913 shows that 66,139 tons of ore was raised and sent to the mill, and gold worth £90,433 was extracted, being at the rate of $6.56 per ton. The year before, 68,486 tons was raised and the yield per ton was $7.48. The working cost was £90,452, and £3584 was allowed for depreciation, so that the year ended with a small deficit. The fall in the yield was due to the stopes on the 770-metre level proving to be poor. On the lowest level now being opened, at 920 metres, the ore shows a substantial improvement, so that the outlook is brighter. The Paredao shoot on the 215-metre level has also given cause for expecting an improved ore supply. The labor question has continued to cause anxiety, for railway and other surface works provide real attractions. The Passagem lode is flat and the men descend and ascend the shafts on foot. In order to avoid this unnecessary exertion, cars are now being provided. The feeding arrangements have also been improved. It is hoped that by studying the men's comfort in these and other ways, labor shortage will no longer be felt. The directors, during the year, commissioned Thomas Richards to examine the mine with a view to determining, in conjunction with Mr. Bensusan, the best way of conducting operations in the future, in the hope that the mine may be restored to financial prosperity. He recommends that the scale of mining should be extended, and the monthly output raised to at least 7000 tons, and if possible to 10,000 tons. To effect this, it would be necessary to sink a new incline shaft in the neighborhood of the Paredao shoot and to provide additional hoisting and metallurgical plant. The capital expenditure required for this purpose is estimated at £30,000. This money is to be raised by the issue of new preference shares, and at the same time the present capital is to be drastically reduced. The £100,000 ordinary shares are to be written down to £15,000, and the £36,634 preference shares are to be exchanged for £12,212 in new preference shares and £24,422 in new ordinary shares. With the expanded system of working it is hoped to reduce the cost to $5.04 per ton, and to extract gold worth $6.24 per ton. On December 31 the ore reserve was estimated at 114,528 tons, as compared with 125,193 tons a year previously.

HOUGHTON, MICHIGAN

WHITE PINE MINE AND NEW MILL.—WORK AT THE ISLE ROYALE.—CALUMET & HECLA MILLS.—WORK AT THE PHOENIX, FRANKLIN, AND NEW ARCADIAN MINES.

Good progress is being made in the development of the White Pine mine, one of the Calumet & Hecla subsidiaries. This mine is in the Porcupine mountains, some distance southwest of the most southerly of the other Lake Superior properties, and is peculiar in that the copper is not disseminated through trap rocks, but is in a vein in the Freda sandstone. The ground is considerably faulted, and development of the property required careful engineering as well as good geological knowledge, but the copper content is high and the mine is a promising one. A mill is being built near the shafts, and will also be unusual in that coarse crushing will be done in the mill in gyratory crushers, instead of in jaw crushers in the usual Lake Superior rock-house. As the ore contains almost no mass copper, the method of crushing offers obvious advantages.

Another Calumet & Hecla subsidiary of much promise is the Isle Royale, which is being pushed to such an extent that the capacity of its mill, and one-stamp head in the Allouez Centennial mill as well, is being overtaxed. The Isle Royale is an old mine which has never paid a dividend, and though the Isle Royale lode is of good width and is persistent for miles, it is low grade, and it is only by selective mining underground and sorting out the poor ore at the surface that the copper content is maintained at its present level of 14 lb. per ton. The obvious thing, which is being done, is to mine and mill the ore on a large scale, cutting operating costs so as to make a profit even with the low yield. When the Benedict leaching process is in full operation, the tailing losses will be reduced to so low a figure that 14-lb. ore should yield a good profit.

The construction of the leaching plant at the Calumet & Hecla mill is proceeding apace, under the direction of C. H. Benedict, who devised the process to be employed. Secrecy is still maintained as to the details of the process, but it is generally known that the solvent is an ammonia salt, and that the success of the operation depends upon good results attained in the recovery and re-use of the ammonia. Mr. Benedict has not given out any figures, but it is stated that he expects to make a recovery of 75% of the copper in the sand, at a cost of 30 to 35c. per ton. The Bucyrus suction dredge for the reclaiming of the sand from the bed of Torch lake is nearly completed, and the regrinding plant is well advanced. Some of the Hardinge mills are already in operation regrinding the sand from current ore, and most of the other mills are in process of erection.

The Keweenaw Copper Co., controlled by Thomas F. Cole, is exploring the old Phoenix mine. A shaft which has reached a depth of 530 ft. is yielding ore which is full of shot copper, and if the lode proves uniform, this old property will make a large new mine. The properties at the north end of Keweenaw point all ceased work many years ago, and it will be most interesting if mining can be revived in that part of the district. Another discovery which may revivify another old property is in the Franklin. Under Enoch Henderson, the superintendent, a cross-cut has been driven to the east on the No. 32 level, and cut the Allouez conglomerate at a point where it is about 18 ft. thick, and contains 30 to 35 lb. copper per ton. The conglomerate has been driven on for about 500 ft., and a raise has been put up 75 ft. A cross-cut on the No. 37 level will be started soon, and if the copper content of the conglomerate is found to keep its value at that depth, the Franklin will have an excellent chance of resuming its former annual output. The New Arcadian is to sink its shaft to the 900-ft. level, on the strength of the copper content of the ore uncovered on the 750-ft. level for a length of 200 ft.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Juneau

The Alaska Treadwell mills crushed 79,254 tons of ore in June, yielding gold worth $119,115 by amalgamation, and $95,335 by cyaniding 1784 tons of concentrate. The estimated net profit was $125,630. Development in the mine totaled 361 ft., and the stock of broken ore decreased 38,464 tons.——The Alaska Mexican mill crushed 19,824 tons, yielding a total of $41,383, of which $14,773 was profit. No development was done in the mine, but expenses include work in the 700-Ft. Claim for the Company by the Treadwell company.——The Alaska United mills crushed 38,601 tons, yielding $76,480, with a profit of $15,778. There was a loss of $1829 on work at the 700-Ft. Claim, the ore averaging $1.67 per ton. Stock of broken ore in the Ready Bullion mine increased 27,460 tons.

ARIZONA

Cochise County

Gold-bearing ore has been discovered at Juniper Flats, near Bisbee, by Truax and Zayne, and hundreds of claims have been located. The granite-schist contact is said to be favorable for further development.

Gila County

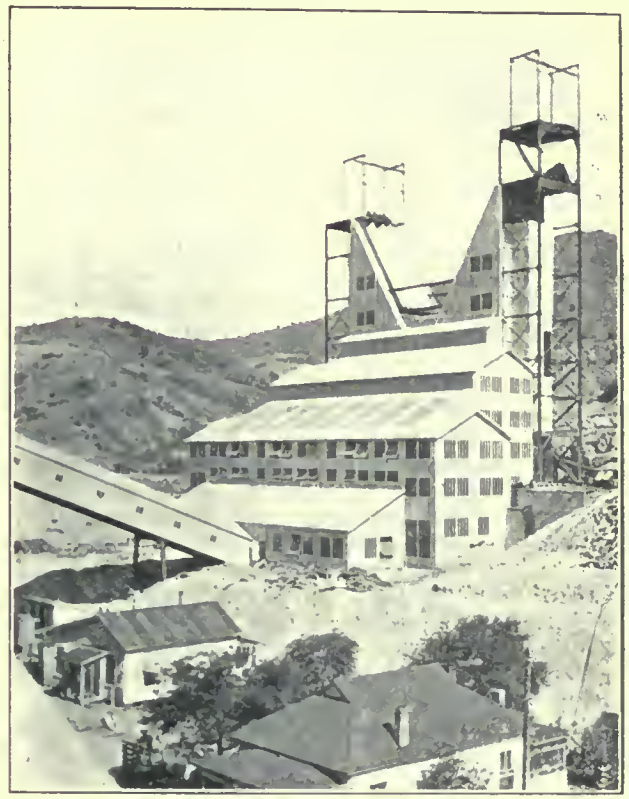
(Special Correspondence.)—Machinery is being installed in the Inspiration compressor and hoist house at a rapid rate. A Nordberg 3000-cu. ft. compressor is at work. An Ingersoll-Rand 1325-cu. ft. machine to compress to 1000 lb. pressure for underground haulage is being set up. These machines are of the cross-compound type with a motor between. A Nordberg hoist is being installed, with C. V. A. Reed in charge. There are in reality two separate hoists, one for each shaft, but it will be possible to handle both from a single operating platform, as when running automatically they will act as a single machine. Hoisting will be done in balance, and as there are two shafts, this means that four skips will be in continuous operation. The skips will weigh 1500 lb. each and will have a capacity of 2400 lb., the net load to be hoisted. To allow ample time for repairs and emergencies, the hoisting period has been limited to 14 hours per day, and the capacity for the set for the period is 10,000 tons from a depth of 600 ft., corresponding to a skip of ore to the surface every minute. The hoist is so designed as to be entirely automatic in its operation, requiring no attendant whatever, either on surface or underground at the loading pocket. It can, however, be disconnected at will so as to eliminate the automatic feature, making it hand operated. So far as known, this is the first large hoist to be entirely automatic in its operation. Although the initial cost is much higher than it would otherwise have been, the amount saved in wages of engineers and attendants will soon offset the extra outlay. Work has been started on the concreting of the 5,000,000-gal. reservoir. The entire reservoir is to be concreted, reinforced with Clinton fabric. It presents a unique problem in ferro-concrete construction, as the sides are all sloping, with the two ends semi-circular.

Miami, July 23.

Mines of the Globe district are being examined by the state mine inspector, G. H. Bolin. He is accompanied by the deputy inspector, John Harper.

Pinal County

(Special Correspondence.)—Churn-drills are being set up on the Gila Canyon Copper Co.'s 16 claims in the Banner district, about four miles from the Arizona & Eastern railway.



HEAD-FRAME, COARSE-CRUSHING PLANT, WITH BELT-ELEVATOR HOUSING TO MAIN ORE-BINS OF INSPIRATION CONSOLIDATED, MIAMI.

About 5000 tons of ore has been smelted from the property in the past.

Christmas, July 23.

CALIFORNIA

Oil production of the state, for the first time, exceeded 300,000 bbl. per day in June, when the total was 9,431,863 bbl. The amount shipped or consumed was 8,616,610 bbl., another record. Field operations showed 22 rigs completed during the month, 218 wells drilling, 46 completed, 6 abandoned, and 5951 producing.

Amador County

The Hardenburg mill has been shut down for several weeks, and all but one engineer have been laid off. The next move in connection with the property is awaited with interest.

Lassen County

A number of copper claims in the Last Chance district are being prospected, and there is talk of a concentrating plant being erected later on.

Modoc County

The Modoc Mines Co. at High Grade, is shipping five cars of ore to the smelters. A vein about 8 ft. wide has been opened to 100 ft.; and in it is an 8-in. streak averaging 4 oz. gold and 4 oz. silver per ton.

Nevada County

The Union Hill mine, east of Grass Valley and adjoining

the Brunswick mine, has been sold to San Francisco and other California men.

SHASTA COUNTY

On August 1, the Victor Power & Development Co. took control of the Midas mine at Harrison Gulch. Old tailing dumps contain about $3 per ton in gold.——A new electric hoist, driven by a 275-hp. motor, has been installed at the Gladstone mine at French Gulch.

TUOLUMNE COUNTY

(Special Correspondence.)—High-grade ore has been opened in the Hart & Jacobs mine, seven miles northeast of Columbia, by A. E. Caldwell. A box of the ore has been placed on exhibition at a local bank, and is convincing evidence that the find is a bonanza. The small mill on the property is now in operation.——C. E. Rives, a mining man from Arizona, has taken a bond on the Schindler ranch, at the base of Bald mountain, and is developing a vein which is giving encouraging prospects. The ranch contains nearly 600 acres and is traversed by several quartz veins.——Rock showing gold is being taken out of the Darrow mine, north of Rawhide, by the Darrow brothers. The shoot has been opened sufficiently to convince the operators that they have made a valuable find.——The Springfield Tunnel & Development Co. is moving its milling plant to the mouth of the long adit being driven to cut the old workings. The adit is now 1400 ft., and will be about 6000 ft. when it reaches the objective point. Raises will be run from the adit when it reaches the Buchanan channel, 700 ft. ahead of present face of adit. A foundation is being laid for a mill twice the size of the one now being re-erected, which would increase the capacity to 500 tons per day.——Suit has been instituted in the Superior Court of this county by 51 lien holders against the Santa Ysabel Mining & Milling Co., C. E. Shafer, Charles Benton, and L. R. Saunders. The plaintiffs hope to hold the property responsible for debts contracted while the mine was being operated by Benton and Saunders, on the point that the Company failed to post notices of non-liability. The question on which the result of the suit depends is whether the notice of non-liability posted by a former operator named Mitchell, who recently sold his interests to Benton and Saunders, was sufficient to protect the Company.

Sonora, July 18.

COLORADO

LAKE COUNTY (LEADVILLE)

Bags are now being hung in the bag-house at the new zinc smelter, and the plant should be started any day.——At the Mt. Champion mine additional equipment is being installed, and officials of the Company from the East are inspecting the property. A tunnel to connect the mine and mill, to take the place of the present tramway, may be driven through the hill. A large tonnage could be treated, and a 250-ton mill may be erected. Lucien Smith is manager.——There is a good deal of activity in the Twin Lakes district. Going into the Lackawanna Gulch district by way of Twin Lakes, Bull hill is at the east end. The Fidelity Gold Mining Co. has 14 claims here. A cross-cut has been driven 800 ft., with 350 ft. to go to cut the main vein. Several small veins have been cut. Sam Smith is manager for C. J. Fox of Philadelphia. The adjoining property is the Golden Fleece, where an adit is to be driven this summer. Other development in this area is being done at the Lackawanna Gold, Miller Gold, Evening Star, Lone Star, and many other properties.

PITKIN COUNTY

The Hope adit at Aspen was advanced 113 ft. in June. A small streak of 127 oz. silver and 22% copper ore was cut. Prospects are bright.

SAN MIGUEL COUNTY

Cn July 27 a cloudburst wrecked about 100 buildings at Telluride, besides killing two persons and doing other damage in the district. The damage is estimated at $300,000.

TELLER COUNTY (CRIPPLE CREEK)

An extra quarterly dividend has been paid by the Portland company, making with the usual one a total of $120,000. A large body of good ore is being developed at the bottom of No. 2 shaft.——The Neville mill, on the Wilson claim of the Free Coinage company, is to be increased to over 100 tons daily capacity. A Chilean is to work in place of a Hardinge mill.——Car tracks, air pipe, and drainage ditch are now up to the heading of the Roosevelt drainage tunnel. Timber is being placed under bad ground there, the Black Belle dike of granite.

IDAHO

SHOSHONE COUNTY

The National Copper Co. proposes to increase its capital from $2,000,000 to $2,500,000, and a meeting of shareholders will be held on August 22. The Company wishes to purchase the adjoining Nellie lode claim of the Continental Mining Co.——The Cedar Creek property is in the Murray district. It has been opened by adits No. 1 and 2, totaling 5000 ft. of general development, and two veins being opened. The ore contains lead, and a good shipment has been made. No. 3 adit is in 200 ft., but will go 2300 ft. farther to cut the veins. The property is equipped with a good plant.——Work is again under way at the Pilot at Murray.

MONTANA

SILVERBOW COUNTY

The Clark Montana Realty Co. and the Elm Orlu Mining Co. have filed suit in the federal court asking for an order restraining the Butte & Superior Copper Co. from operating on the Elm Orlu and Rainbow lodes, also asking for an accounting for all ores previously extracted by the Butte & Superior from these claims.——A good shoot of zinc ore has been opened at 2400 ft. in the Pilot-Butte mine.——Butte & Superior production for the first half of 1914 is as follows: ore treated, 193,090 tons; concentrate, 60,667 tons; zinc in concentrate, 52.4%; and recovery, 89.3%, against 111,400 tons, 38,397 tons, 46.9%, and 80.58% respectively for the same period of 1913.

NEVADA

ESMERALDA COUNTY

During June there was 2417 ft. of work done in the Goldfield Consolidated mine at a cost of $6.44 per foot. The mill treated 25,955 tons, yielding $147,100 net. Costs totaled $6.12 per ton. Lessees mined 368 tons, worth $8243. There was 1750 tons of Jumbo Extension ore treated also. A general clean-up of the plant is under way and should yield about $100,000. A new pipe-line is to be put in for the precipitating plant to replace and clean the one in use since the start of the mill. During the second quarter of 1914 the mill treated 84,326 tons of ore, yielding $945,179, realizing $445,813 net. Ore reserves in the Aurora mine recently acquired, are estimated to yield $893,000 net, the average value being $4.81 per ton, of which $1.50 should be profit. The last cash payment of the $763,011 for the property is due on October 25. After making the first payment of $388,800, the Goldfield Consolidated company had $445,000 cash in its treasury, and bullion in transit worth about $154,000. As there is not enough money for a dividend, this will be passed.

HUMBOLDT COUNTY

A 100-ton custom mill is to be built at Rochester according to John F. Cowan, president of the Rochester Mines Co. A good site has been secured, also plenty of water four miles away.——In the Codd lease, work is in 100 ft. on the vein at a depth of 425 ft. Ten feet of ore averages $20 per ton. ——Rich ore is still being shipped from the Packard lease.

Lyon County

The Mason Valley smelter received an average of 501 tons of ore per day during the third week of June.——Chalcopyrite has been opened in the Ludwig section of the Nevada-Douglas property, near the gypsum deposit.——Good progress is being made at the Greenwood, Bovard, Empire-Nevada, Montana-Yerington, and East Side properties.

Mineral County

A new 10-stamp mill and cyanide plant is working at Candelaria in charge of George Threfall, who states that the owners have started plans for a 200-ton mill.

Nye County

There was a very heavy electric storm in southern Nevada on July 20, and the Nevada-California Power Co.'s power lines from California needed considerable repairs, and power was off from Tonopah and districts for several hours. This was the worst storm since September 13, 1913.——On July 22, three miners were overcome by gas in a 90-ft. shaft at Crow Springs, 23 miles northeast of Tonopah, and Bureau of Mines rescue-car No. 5 immediately went to the rescue. One died and the other two recovered. The men were Servians.

Tonopah mines produced 50,133 tons of ore worth $877,580 in June. Last week's output was 12,038 tons worth $306,290, a record for the district.——Mine-rescue car No. 5 was in Tonopah last week, being on a side track of the Tonopah Mining Co.'s Mizpah mine. Mr. Blackburn, the superintendent, placed part of the 400-ft. level at the disposal of the engineers for demonstrations and instruction. Teams from all the larger mines were shown the work.

Storey County

The Mexican and Union companies are preparing to prospect and open ground at 2650 ft. on the Comstock lode. Pumps are to be installed at certain points.——The Con. Virginia is mining ore at 2500 ft.——The Ophir is doing most of its work at 1600 feet.

White Pine County

According to C. B. Lakenan, general manager of the Nevada Consolidated and subsidiary companies, nine steam-shovels are moving about 10,000 tons of 1.6% copper per day. A recovery of 69% is made at the mill. At the Giroux, six Star churn-drills are working, the Boston-Ely is diamond-drilling, and underground work is under way at the McDonald-Ely. Generally the Ely district is active and looking well.——A mill will probably be erected to treat the lead-silver ore of the Macon City claim in Robinson cañon.

OREGON

The mine output of gold, silver, copper, and lead in Oregon in 1913, according to Charles G. Yale, was valued at $1,746,402, compared with $849,886 in 1912, an increase of over 100%. With the exception of copper, all these metals showed an increase in output. The gold yield for 1913 was $1,627,710, of which $1,177,082 was derived from deep mines, and $450,628 from placers of various kinds. The yield of silver aggregated 179,036 fine ounces, valued at $108,139, an increase of 121,955 oz. in quantity and $73,034 in value over that of 1912. The mine production of copper in 1913 was 43,330 lb., valued at $6176, a decrease of 217,099 lb. in quantity and $36,255 in value, from that of 1912. In 1913 Oregon produced 87,207 lb. of lead, valued at $3837, compared with 39,317 lb., valued at $1769, in 1912. There were fewer mines in operation in 1913 than the year before, but the tonnage from deep mines was materially enlarged, and the placer mines, including one new dredge property, made a record year.

Baker County

An examination of the Ben Harrison mine has been finished by an engineer of the United States S. R. & M. Co. This concern is operating the Rainbow mine in Mormon basin. A large mill will probably be erected at the Azurite mine, near Homestead, to treat gold-silver-copper ore.——The North Pole mill is shut down.——Engineers are to examine the Cougar mine in the Granite district.——A test mill is working at the Last Chance mine at Cable Cove, and machinery for a 20-stamp mill is being delivered.——Dredging machinery is being assembled at the Gold Center property on Bull Run creek.

Josephine County

(Special Correspondence.)—The Old Channel hydraulic mines, of Galice district, have been sold to Chicago people for $10,000. Of this amount, only a part has been paid down, the remainder to be handed over within the next two years. The deal was completed by J. R. Harvey, the former manager of the mine. The Old Channel is one of the best equipped hydraulic properties in southern Oregon. It was for years one of the largest gold producers, but during the past few seasons has been practically idle, this being due mainly to

MAP OF OREGON.

litigation and dissatisfaction among the shareholders. The property includes about 600 acres of timber and mineral lands, with fine water rights. There are over 20 miles of ditches and flumes, and many thousand feet of pipe-lines. Three No. 6 giants are operated when the mine is at work, these working under a head of 500 ft. The gravel is deep, occupying the fill of an ancient river bed.

About 360 oz. of gold, the weekly clean-up from the Braden mine, is being shipped each week through the local banks to the mint at San Francisco. The management of the Braden is not only doing a great deal of improvement and development work on this property, but is showing also that there is a long life for it.

Grants' Pass, June 24.

UTAH

Juab County

At the Knight-Christensen mill at Silver City the recovery of copper and gold and silver is 90 and 85% respectively, at a cost of about $2 per ton. The present ore does not contain lead or zinc. N. C. Christensen, who devised the process, is satisfied with results.

Salt Lake County

Development amounting to 1400 ft. per month is being accomplished at the Utah Consolidated. Lead ore containing 18 to 20% metal has been opened for 200 ft. on the 700-ft. level transportation adit. It averages 3½ ft. wide. Reserves of lead ore at July 1 about 500 ft. are 10,000 to 12,000 tons, and from 500 to 700 ft., 60,000 to 65,000 tons, a good increase on previous estimates. Work in the copper area is opening more ore. Flotation tests on 1.75% copper ore at the Highland Boy

mine show promising results.——The Ohio mill at Lark treated 74,600 tons of ore in June, a record run. The new crusher and rolls should be ready in a week or so.

SUMMIT COUNTY

The Mines Operating Co.'s plant at Park City, according to Theodore P. Holt, was designed to treat the low-grade filling in old stopes of the Ontario mine. This material assays 6 to 14 oz. silver, 1 to 2 lb. copper, 0.01 to 0.015 oz. gold, and a little lead and zinc. Treatment consists in mixing the crushed ore with coal dust and salt and then roasting in a new type of furnace by combustion of the contained fuel. The roasted ore is leached with an acid salt solution to dissolve the silver, gold, copper, and lead. At present these metals are precipitated together on scrap iron and the product sold to a refinery. The only new feature of importance in this scheme of treatment is the roasting process, which makes possible the chloridizing of ores without any loss of the valuable metals, and at a very low cost.

CANADA

NOVA SCOTIA

The following minerals, all previously unknown to occur in the province, have been identified by Alexander McLeod: magnesite, tourmaline, stannite, allanite, and molybdenite.

ONTARIO

(Special Correspondence.)—The gradual decline of the Cobalt silver-mining industry owing to the exhaustion of some of the leading producing mines is indicated by the closing down of the Temiskaming & Hudson Bay mine and mill, and the slump in La Rose Consolidated, which recently dropped below $1, and is now selling at about 92c. per share. It has been officially announced that the ore reserves of the La Rose are at a low point and that, failing new discoveries, the Company will be wound up. The production of ore has been gradually diminishing since the record year 1909, when it amounted to 6757 tons, the shipments for the present year so far being only about 700 tons. There is a cash surplus on hand of something over $1,000,000 in addition to other realizable assets. The Temiskaming & Hudson Bay has another Cobalt property, which may prove of value in addition to a controlling interest in the Dome Lake of Porcupine. The Nipissing has also apparently passed its zenith. The estimated net production for June was $183,558, as compared with $211,256 in May, and it is stated that the results of development at the 900-ft. level have been disappointing.

Cobalt, July 20.

Under direction of the Department of Mines for Canada, W. H. Boyd, chief topographer of the Geological Survey of the Dominion, and Mr. Dickison have arrived at Sudbury to map the nickel area.

YUKON

The Lone Star quartz mine, at the head of Victoria gulch, a tributary of Bonanza creek, near Dawson, is working steadily, and up to June 30 of this season the mill had crushed 1540 tons of ore, of which 1028 tons was crushed in June.

JAPAN

The Kano copper mine, in the Fukushima prefecture, has proved a disappointment. A company with a capital of 5,000,000 yen was organized seven years ago to work it. The company is in debt 200,000 yen, and but 400 miners (formerly 1200) are employed.

MEXICO

SONORA

There has been further trouble at Cananea, and on July 24 the Veta Grande and Oversight mine shafts of the Cananea Consolidated company were on fire. Damage so far is estimated at $300,000. Rescue appliances were sent from Bisbee, Arizona.

PERSONAL

HARRY J. WOLF was in San Francisco.

WILLIAM HAGUE was in San Francisco.

CHARLES JANIN has arrived from London.

C. W. MERRILL was in the city Wednesday.

SIDNEY JENNINGS was in San Francisco Wednesday.

EDMUND JUESSEN was down from Tonopah for last Sunday.

PHILIP WISEMAN has been in San Francisco returning from Mono lake.

HOYT S. GALE is visiting California, being at present at Sacramento.

PHILIP ARGALL & SONS are examining the Buffalo Boy mine, at Silverton, Colorado.

DONALD F. IRVIN has resigned from the Tigre Mining Co., and has returned to California.

R. H. RICHARDS is visiting California in the course of a general trip through the West.

ELMER E. FICKETT, who has been visiting Western mines, passed through San Francisco this week.

S. H. SHERMAN, superintendent for the Gila Copper Sulphide Co. at Christmas, visited Globe and Miami, recently.

MORTON WEBBER, who was recently engaged in a placer examination in Idaho, has gone to Montana on professional business.

Information regarding the present address of THOMAS SANDERSON PARKINS, formerly of Chatham, Canada, is desired by relatives.

FREDERIC E. CALKINS, recently with the American Smelting & Refining Co., has been made mine inspector by the mining companies at Morenci, Arizona.

R. B. STANFORD sailed from New Orleans on July 23 for Choluteca, Honduras, by way of Puerto Barrios, where he will be engaged in examinations for sixty days.

LORIN KEMP, who for a number of years has been in charge of the cyanide plants of the North Star Mines Co. at Grass Valley, California, has resigned, to accept a position in Chile, South America.

SCHOOLS AND SOCIETIES

THE MINING ENGINEERS' ASSOCIATION has been formed in London, with offices at 18 Eldon street, to assist mining engineers and metallurgists abroad and at home in various ways.

THE ROYAL GEOLOGICAL SOCIETY OF CORNWALL, ENGLAND, held its centennial celebration at Penzance on July 3 and 4. Congratulations were received from all of the principal societies of England. Interesting statistics were given on the tin and copper outputs of the county.

THE CHEMICAL, METALLURGICAL AND MINING SOCIETY OF SOUTH AFRICA met on May 16. Hydraulic classifiers and classification was discussed by G. H. Stanley; charcoal in gold-bearing cyanide solutions by Morris Green; rock temperatures by E. J. Moynihan; dust in mines by B. C. Gullachsen; and soda deposits of Africa by John Watson.

THE AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS has been formed with offices at Madison, Wisconsin. Officers for 1914 are: president, W. F. MacGregor; first vice-president, J. L. Mowry; second vice-president, W. J. Brandon; chairman of council, A. R. Greig; and secretary-treasurer, F. M. White. The object of the society is to interest men concerned with the application of engineering principles to agriculture.

Metal Prices

LOCAL METAL PRICES

San Francisco, July 30.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony	9 — 9¾c
Electrolytic copper	15 —15¼c
Pig Lead	4.15— 5.10
Quicksilver (flask)	$37.50
Tin	35 —36½
Spelter	6½— 6¾c

Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 30.—All metals are quiet and weak, copper showing a decided slump. Gold amounting to $14,750,000 has been engaged for shipment to Europe, totaling $27,850,000 since July 23, and over $110,000,000 since the beginning of the year. A large turnover of stocks and bonds is being made on the Stock Exchange. European exchanges have been temporarily closed, but London is still open. Bar silver is weak in London at 24d. (48c.). Lead and spelter at St. Louis are 3.75c. and 4.90 to 4.95c. respectively. Greene Consolidated Copper Co. has passed its dividend.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

The gold production of Australia and New Zealand for the first five months of the year is as follows:

State.	1913. Fine ounces.	1914. Fine ounces.
Victoria	170,146	171,951
New South Wales	57,849	50,244
Queensland	111,662	96,767
Western Australia	524,883	523,160
*South Australia	3,500	3,500
*Tasmania	15,000	15,000
Commonwealth	883,040	860,622
New Zealand	140,953	130,990
Total	1,023,993	991,612

*Approximate.

New York Metal Review

Though the domestic consumption of copper continues far under normal, as statistics show and the market almost daily demonstrates, there are some bright spots from which encouragement may be drawn. July set in with heavy buying of copper for export. Prices of finished products have gone no lower. Lead has been steady, partly because of support from abroad, where scarcity and high prices prevailed. Spelter has held its own, and galvanizers have taken good-sized quantities. Tin, as is often the case, has been erratic, but transactions have been numerous. Antimony was dull and uninteresting. Aluminum saw some activity. In various lines of trade there are indications of a betterment in demand, which, while it is irregular, is believed to be the forerunner of a gradual and natural improvement in trade conditions. A revival in business, however, cannot be as sudden as some prophets would have the industrial world believe, and many of the printed reports of returning prosperity have little basis when analyzed. But that there is real improvement here and there, and a better feeling nearly everywhere, cannot be denied, despite inspired reports which are given publicity for their 'psychological effect.'

COPPER

Two features stood out in the copper situation of early July. One was extremely heavy buying for export in the first week, and the other was the disappointing showing of the June statement of the Copper Producers' Association. This came on the heels of disappointment that American consumers did not take hold as the foreign buyers did. They did some buying, but it was conservative. In this connection it is pointed out that Europe usually takes advantage of low prices, while domestic consumers must be stimulated by a rising market and they do not ordinarily buy so advantageously as do the foreigners. In the movement referred to, Europe took 40,000,000 to 50,000,000 lb., and most of it was obtained at 13.37½ to 13.50c., cash, New York. After Europe ceased buying, the price went up steadily until by July 7 the quotation for electrolytic was 13.87½c., 30 days, delivered, or 13.75c. cash, New York; but there was not much doing and such activity as there was died out when, on July 8, the Producers' statement showed an increase in stock of 21,768,022 lb. The poor showing was entirely due to the lessened domestic deliveries, which in June were but 46,227,353 lb., or 9,364,817 lb. less than in May. It is estimated that home consumption is about one-third under normal, and there can be no betterment until there is a pronounced increase in melting by the brass and copper mills. Consumers must first find justification for departing from their policy of not stocking up beyond actual current requirements. When general business improves, the meagre state of stock in manufacturers' hands will mean an unusual demand and great strength to the market. By July 10 prices were on the down grade again, and 13.50c. cash, New York, and probably lower, could be done by July 15 and for a week thereafter. The quotation July 24 was 13.37½c. cash, New York. The market in the third week of the month (July 15 to 21) was in a state of stagnation, Europe showing no more interest than domestic consumers. Following electrolytic, prime Lake went to 14c. cash, from 13.87½c. in the first week, but by July 15 it was down to 13.75c. for prime and less for inferior grades. Exports in June totaled 35,182 tons, and those of July up to the 24th amounted to 28,175 tons. The Waterbury average for June was 14.37½ cents.

LEAD

The New York quotation was steady at 3.90c. from July 1 to 24. When the month opened, the St. Louis price was 3.77½c., but in a couple of days it settled to 3.75c. and remained there, this price being one with New York at 3.90c.,

which enables independent producers to undersell the large interest at all points except New York. Perhaps prices would have gone lower were it not that a scarcity prevailed in Europe with correspondingly good prices there. The quotation in London, July 10, was £19 to £20 for English lead, with the tone strong. Exports in July were good. Late in July the New York quotation was unchanged, but there was possibility of concessions from the St. Louis price, the New York market still being supported by London. The Bureau of Foreign and Domestic Commerce, Department of Commerce, reports the total amount of lead remaining in warehouses May 30, 1914, at 13,339,418 pounds.

SPELTER

A better feeling was created at the outset of July by the averting of trouble over wages between the sheet mills and their employees. The New York price was fairly steady at about 5c. from July 1 to 24, although the St. Louis price, near the third week, was relatively five points lower, 4.80c. having been quoted. At this latter basis some good-sized orders were reported to have been taken, with smaller ones at 4.82½c., most of the demand coming from the galvanizers. Business in sheets is better. The brass mills showed little interest. A rumor afloat, but not generally credited, was that some of the smelters were unwilling to give their production figures for the first half of 1914 to the United States Geological Survey, and that mid-year statistics might be delayed. It is no secret that producers' stocks are extremely large.

TIN

The market was erratic, at times feverish, in July, but some good business was done. In the first three days there was good action in both prompt and future deliveries, and the market assumed more optimistic tone than had prevailed in weeks. Under this stimulus, London advanced £4 on July 6. The trend of prices is indicated by the following figures at which sales were made: July 1, 31.10c.; July 6, 32.20c.; July 9, 32.55c.; July 14, 31.50c.; July 18, 32c.; July 21, 31.60c.; and July 24, 31.15c. Beginning about July 8, the market was particularly lively, with days of good buying interspersed with hesitancy on the part of buyers or unwillingness to sell on the part of operators. On July 14, London declined £3, which was attributed to the report of the Interstate Commerce Commission on the New York, New Haven & Hartford railroad and illustrates the sensitiveness of the tin market. Much of the buying of the second and third weeks of the month was speculative, dealers figuring as purchasers in many of the transactions. The arrivals in July up to the 24th were 3144 tons, and there was afloat 2650 tons. The total visible supply June 30, 1914, was 16,027 tons, as against 11,101 tons June 30, 1913. June deliveries totaled 3650 tons, and the total deliveries for six months of this year showed a decrease of 600 tons, as compared with the same time last year. Government statistics show that the imports of tin at Pacific ports in May (by districts) were as follows: Oregon, 31,494 lb.; San Francisco, 67,233 lb.; and Washington, 88,745 pounds.

ANTIMONY

This market was uninteresting and neglected. Quotations throughout the month were about 7c. for Cookson's, 6.75c. for Hallett's, and 5.40c. to 6c. for other grades.

ALUMINUM

About the middle of July some good-sized inquiries were reported which caused European makers to offer low prices, some sellers being willing to go under 17.50c., duty paid. The quotation for domestic metal, 98 to 99% pure, on June 15 was 17.50 to 17.75c. for prompt and future, but by July 20 futures had declined to 17.37½ to 17.62½c. Average prices of domestic aluminum by months were as follows: January, 18.86c.; February, 18.80½c.; March, 18.30c.; April, 18.08c.; May, 17.93c.; and June, 17.82c. per pound.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.
6s-12 oz.-40s	8¾	6s-14 oz-20s	9½
6s-12 oz.-20s	9	6s-16 oz.-40s	10
6s-14 oz -40s	9¼	6s-16 oz.-20s	10¼

Extra hard 1c. per set higher than the above.

The Messina copper mine output in May was as follows: ore milled, in 25 days, 6377 tons; concentrate produced, 1046 tons; average copper, 39%; reverberatories smelted 416 tons of middling producing 80 tons of 54% matte, total output 1126 tons averaging 40% copper. Development in the mine was satisfactory.

MINERAL STATISTICS

Coal Production of the United States

The production of coal in the United States has again broken all previous records, the output for 1913 being 570,048,125 short tons, which is considerably more than double the production of 1900 and more than eight times the production of 1880, according to Edward W. Parker, coal statistician. The value of the coal mined in 1913 is given as $760,488,785. Compared with the previous year the output for 1913 shows an increase of 35,581,545 tons, or nearly 7%. The increased activity indicated by these figures was well distributed throughout the 29 coal-producing states, 23 of which showed increases and only 6 decreased production, the decrease in one of these, Colorado, being due solely to labor trouble. Of those showing increase, 12 made record yields, and Pennsylvania, the leading coal state, broke records in both bituminous and anthracite production. The states which broke all former records in coal production were Alabama, Illinois, Kentucky, Montana, New Mexico, Ohio, Oklahoma, Pennsylvania, Texas, Utah, Virginia, and West Virginia. The largest increase in the production of bituminous coal was in Pennsylvania, where 11,915,729 tons was added to the output of 1912. West Virginia showed the second largest gain, 4,522,295 tons, and Kentucky the third largest gain, 3,126,079 tons, which was also the largest percentage of increase, amounting to 19%, of all the important coal-producing states. Indiana was fourth, Illinois fifth, Ohio sixth, and Alabama seventh. While the total increase was very large as figured in tons, the percentage is what may be considered normal and indicative of healthy industrial activity throughout the country.

Coal mining, like all other industries in the Ohio Valley states, was seriously interfered with by the great floods during the spring of 1913, and Mr. Parker estimates that from 5,000,000 to 10,000,000 tons of coal would have been added to the year's output but for this disaster. With no violent fluctuations in the demand by blast-furnaces, steel works, and other manufacturing industries, the demand for coal for those purposes shows only a normal increase. The continued decrease in the use of fuel oil in the Mid-Continent oilfield and the strike in the Colorado coal mines resulted in an increased output of coal in the Central and Southwestern states. With a few exceptions, notably in Illinois, Indiana, and Oklahoma, prices ranged higher than in former normal years, so that from the producers' standpoint the conditions in 1913 were fairly satisfactory.

The development of our coal-mining industry with reference to population presents some interesting comparisons. In 1850 the coal output was 7,018,181 tons, or 0.3 ton for each of the 23,191,876 inhabitants; in 1880 the population had increased to about 50,000,000 and the production of coal to about 71,000,000 tons; an average of 1.42 tons per capita. At the close of the nineteenth century the population was 76,303,387, an increase of a little over 50% as compared with 1880, while the production of coal had increased nearly 400% in the same period and averaged 3.53 tons for each person. In 1913 the per capita production was figured at 5.85 tons.

The coal mines of the country gave employment in 1913 to an army of 747,644 men. The average number of days worked by the bituminous miners in 1913 was 232, against 223 in 1912, while the average time made in the anthracite mines in 1913 was the best on record—257 days for each man. The average production per miner in the bituminous mines increased from 820 tons in 1912 to 838 tons in 1913, both being record-breaking averages, while anthracite miners increased their average from 485 tons in 1912 to 532 tons in 1913.

MEMBERS of the American Institute of Mining Engineers are anticipating a pleasant visit to Salt Lake City next week and their hosts have made preparations that fully assure realization of these anticipations. Excellent provision has been made for both the technical and social phases of the meeting.

A SUNDAY holiday for the employees of the Utah Copper Company went into effect the first of August and work at both the mines and mills of the Company will be completely suspended on Sunday in the future. While this order means that about 100,000 tons less of ore per month will be handled and the output of copper will be decreased by 1,500,000 pounds per month, the 4000 employees will be glad for the opportunity to take an occasional 'dip' in Salt Lake or sit on the bleachers and root for the home team.

RESIDENTS of Marysville will receive about $210,000 from the sale of the gold-dredging lands on the Yuba river adjoining the Hammond property. The property purchased by the Guggenheim interests includes the Sunset claim of 128 acres, the Gilt Edge of 107 acres, and the Archimedes claim. The property of the Mammoth Gold Dredging Company, which amounts to 190 acres, and that of the Marysville & Nevada Power & Water Company, which is adjacent to the claims purchased by the Guggenheim interests, are also pending sale. The gold-dredging industry in California has not become so entirely a matter of history as many believe.

OPENING of the Cape Cod canal on July 29 marks the completion of an important undertaking, and coastwise shipping along the Atlantic will be greatly benefited. This waterway connecting Buzzards bay with Massachusetts bay will enable vessels to avoid the dangerous passage around Cape Cod and reduce the shipping distance between ports north and south of it by 70 miles. The canal is 13 miles long and 100 feet wide at the bottom, with 300 to 400 feet at the passing points. The depth is 25 feet at low tide. There is an appreciable current, due to the difference in tide in Massachusetts and Buzzards bays. It is estimated that between twenty-five and thirty million tons of freight and about 500,000 persons are transported over the Cape Cod route annually. It is recorded that during the past 60 years more than 2000 vessels have been wrecked while making the passage around the cape and nearly 1000 lives have been lost. The $12,000,000 which has been spent in the construction of this canal has been to good purpose and Mr. August Belmont and his company are to be congratulated upon the successful completion of this work.

JAPANESE advices are to the effect that a large body of 'black ore' has been developed at the Hanaoka mine owned by the Kobayashi interests, as a result of drilling. The orebody is reported to be 4000 feet long and similar to that which, at the neighboring Kosaka mine, long yielded so plentifully. A small smelting plant is to be built, but in the main the ore will be handled at Kosaka where the metallurgists first learned to smelt this difficult ore. With 30 per cent barium sulphate, nearly 10 per cent of zinc, and a trifle over 2 per cent each of lead and copper, it was only by mixing ores and by large scale operations that the Fujita metallurgists met the situation. Whether the Hanaoka will develop into a mine as big as the Kosaka, long the largest in the Far East, cannot yet be said, but the find proves the old rule that orebodies do not occur singly, and we may hope that the mantle of Kosaka has fallen on Hanaoka.

MINING LAW REVISION AGAIN

Legislation regarding general revision of the mining laws is halted at Washington though our correspondent notes that remedial acts covering the present difficulties in the oilfields and existing locations in phosphate lands are at least in position for prompt passage. There should be no delay. In both the oil and phosphate regions grave injustice is being done and in the case of the oil, serious injury to public as well as private interests may well flow from continuance of present conditions. The remedial acts have been carefully drawn, amply considered, and should be promptly passed. This, however, would not relieve the situation materially as regards the much needed general revision. In regard to this, matters remain much as they have been for the last two months except that it has become clearer that the administration leasing bill covering coal, oil, and phosphate lands, is unlikely to be passed at this session. There can, therefore, be no sound reason for excluding consideration of the laws governing these lands from among those to be considered by the prosposed com-

mission for studying the whole matter. So long as there was serious expectation of Congress passing the leasing bill in its present form, it was natural to limit the authority of the commission to the consideration of the laws governing metal lands. If congressional opinion was already determined, a report from the proposed commission would not be likely to change it. In fact, however, it appears that opinion is divided, and, this being so, a careful study by the commission should be helpful.

There are many advantages in making the duties of the commission comprehensive. The mining men are tired of piece-meal revision, of patches placed upon patches till the original cloth is all but lost to view. If we are to change our system let us be frank about it —and let it be a consistent change. Any forcible injection of a new and alien method of dealing with one class of mineral lands, injected into the middle of our present system of public land laws, cannot but produce friction and injustice. It must not be forgotten that the body of the law is more than a mere paragraph or two on the statute books and that changes must be made with an eye to the whole. The mining men have many changes that they wish considered, but they want them really considered; there is no demand for a sudden and radical ripping up of the present system to eradicate parts without regard to the whole. There is widespread dissatisfaction, for example, with the apex law, but there is equally widespread, even if less often expressed, recognition that extralateral rights in future claims cannot be abolished without compensation, such as enlargement of the area of the claim. The danger in any revision is that, attack being concentrated on specific abuses, no adequate account will be taken of the relations to the whole body of the law of the right which it is proposed to abolish. The mining men see this, and it is with this in view that they are urging a commission with broad powers to clear the way for congressional action. Final authority would rest with Congress and the commission would be effective or ineffective according as it was careful and sane in its recommendations or the reverse. The mining laws are sure to be amended; the practical matter is to secure a well considered change rather than an ill-balanced one.

One minor difficulty in the road of the proposed legislation is a difference of opinion at Washington as to whether the members of the proposed commission should serve without pay or should receive moderate compensation for their time. To our way of thinking, this is unimportant. Excellent men will be available under either condition. In England it is an honor to serve upon a Royal Commission without pay, and in the United States there are many big men, men who know and have the interest of the industry and the country at heart, who could and would give the time necessary to the work. At the same time there is no good reason why the commissioners should not receive pay, such as it has been customary to give to those serving on other and similar investigations. The amount involved is insignificant compared to the importance of the subject and to the sums appropriated by every Congress for all sorts of projects. Whether the work cost $25,000 or $50,000 is of small concern, provided it be well done. The important thing is that the commission be authorized promptly, that it be adequately financed, and that it be truly representative.

THE EUROPEAN CRISIS

Not many weeks ago the warships of several European nations steamed into the Baltic to take part in the festivities attendant on the opening of the Kaiser Wilhelm canal. A cordial exchange of courtesies took place at Kiel and the ships departed with the bonds of friendship apparently strengthened and the possibility of international complications a trifle more remote. Today the great powers of Europe are at war. An analysis of the situation would be most tedious, as the factors which go to make it up are more deep seated than the assassination of Austria's crown prince and its immediate results; theories are numerous regarding it, but none seem satisfying and commensurable with the disaster, for such it is, which has befallen Europe.

Forty-three years ago on March 1, 1871, the German army, after a five months' seige of Paris, marched through the Champs Elysees and took possession of the French capital. The French empire had fallen, Napoleon III was a prisoner in Germany, and the National Assembly had fled to Versailles. Terms of peace were imposed which forced France to pay $1,000,000,000 indemnity and transferred the provinces of Alsace and Lorraine to German sovereignty. While the disaster to France was gigantic, the Third Republic was a magnificent fact and national progress was quickly restored. For nearly a half century France has made but little secret of her desire to be avenged and other nations have become sympathetic. The result has been a network of alliances and treaties so interwoven that once the delicate fabric was disturbed, the much prepared for war became a reality. Whether it is the last stand of the imperialist element in an effort to unite the many internal factions in a common cause, or a desire for power and governmental aggrandizement; whether it is an outlet to the Mediterranean, or a trial of strength; whether it is the clashing ambitions of the Romanoff with the Hohenzollern and the Hapsburg, or the conflicting aspirations of the Slav and the Teuton; whether it is that the Slavs in central, eastern, and southeastern Europe wish to unite in racial fellowship and the Teutons would block the way—all these are conjectures, but no one can say certainly.

While the reasons for the struggle may seem theoretical to Americans, they are no doubt real to Europeans, and we can only stand aside and hope that the present conflict will be brief and final, and that when the gonfalon of war is lowered it will be to mark the beginning of a lasting peace.

Stock markets continue closed, a wise and necessary

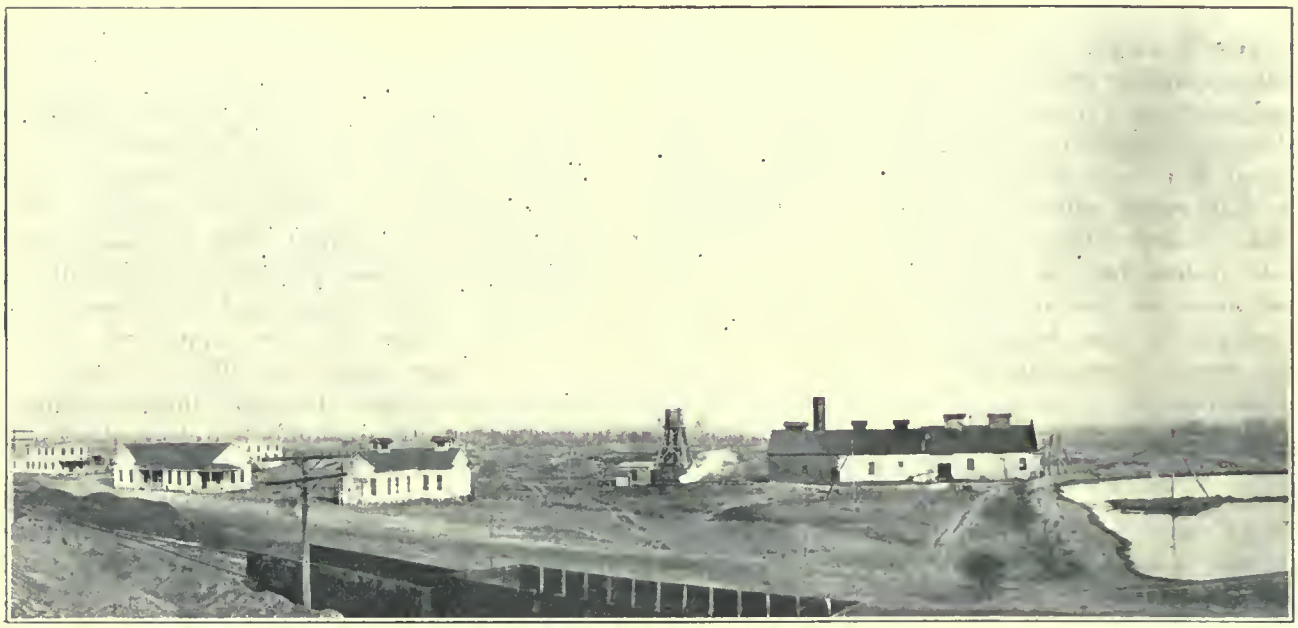
precaution to prevent the wholesale and ill-advised liquidation of sound stocks. This suspension in trading will give shareholders time in which to consider the situation carefully and prevent the unwarranted sale of sound securities. It will conserve present stock values and serve to strengthen the financial situation. It is believed that the suspension of the exchanges will be brief and trading will be resumed as soon as the initial period of uncertainty is past. Holders of mining shares should realize that the depredations of war have no effect upon ore reserves and while markets may be curbed for the time being, the earning power of the mines remain intact, although the production may decline temporarily.

THE FUTURE OF COPPER PRICES

Every owner and operator of copper mines which make only a small margin of profit over working cost has a life and death interest in the average price of copper during the next decade. Will it remain close to the average of the past decade, will it advance, or will it decline? If soothsayers were taken seriously nowadays, they could doubtless do a thriving business. But prognostication is now recognized as a difficult profession. A statement of the principal factors involved, without attempting to draw a conclusion, is, however, within the bounds of caution, and may serve as a basis for individual inferences.

The present output of copper in this country is, roughly, one hundred million pounds per month. The rest of the world combined produces about eight-tenths as much. The cost of production of the leading American producers, in cents per pound, as computed for 1913, was as follows: Nevada Consolidated, 9.51; Utah Copper, 9.25; Miami, 7.9; Anaconda, 12.2 (less gold and silver). These and other companies which it would be tedious to mention individually, are making good operating profits. Many other companies with higher operating costs are either making small profits or struggling to keep going in the hope of higher prices. The consumption of copper has shown a steady growth for many years, and operators hope that consumption will keep far enough ahead of production to maintain prices at or above their present level. But there are new factors in the situation, the influence of which cannot be accurately gauged. Mr. Robert Williams recently predicted that in 1916 the Katanga mines of South Africa will be landing 7,000,000 pounds of copper per month in Europe at a cost of 6½ cents per pound. At the same time the mines at Chuquicamata in Chile will be landing 10,000,000 to 12,000,000 pounds per month in Europe at a cost of 6 cents per pound, according to the estimates of Mr. Pope Yeatman, with the prospect of rapid expansion to three times that monthly output. The two mines alone will add over 10 per cent to the world's output of copper. Other smaller new mines are coming into production, and nearly all the large mines in this country are planning to make a larger output by the use of methods which will recover part of the copper now lost in tailing. Copper consumption in 1913 was roughly 1⅔ that in 1903, corresponding to an average rate of increase of 6 to 7 per cent per year. It is thus seen that there is room for difference of opinion as to whether production is likely to exceed consumption in the near future, according to the amount of confidence placed in the increases in output which are promised. The cost of production has no direct effect on consumption, but a low cost will increase production, which will tend to decrease the price of copper and so increase consumption. Lower selling prices for copper will cause some producers to cease work, which will tend to decrease consumption and so steady the price, through maintaining the nice adjustment of supply and demand. The point is, however, that the low cost producers are the large companies, and when these increase their output beyond what the market will bear without showing a decrease in copper prices, many smaller organizations will have to go to the wall; the survival of the fittest coinciding in this case with the survival of the biggest.

Other even less definite factors are not without strong influence. The output of aluminum is being greatly increased, and it is known that aluminum can be employed as a substitute for copper in many ways. Whether it will be thus employed or will find new uses of its own is hard to foretell. Most difficult of all to foresee is the influence of present political conditions in Europe. The great war now being waged can hardly fail to extinguish colossal amounts of capital and credit and put the whole world on a new financial footing. One reason for the present business depression is that people the world over have been decreasing their expenditures. The consumption of food by hordes of men who are productive of nothing but death and destruction, and the capital consumed in the destruction of property and the conduct of military operations, is likely to send the cost of food soaring and the sales of merchandise tobogganing. If the war continues long the people of Europe can hardly escape a period of privation which has not been equaled in this century and the effects would inevitably be felt on this side of the ocean as well. All in all, it is hard to see how the consumption of copper during the next decade can maintain enough of a lead over the expected increases of output to cause any advance in the average price of the metal. Indeed it is much more likely that production will outstrip the consumption, and in that case the selling price will not greatly exceed the production cost of the major portion of the supply. What that will be cannot be foreseen, but it is not without the bounds of possibility that in 1925 the average price of copper may be 10 or 12 cents per pound. Even if this possibility should eventuate in fact, we do not expect to see disaster overtaking the copper mining industry. The industry has continued to increase and prosper through many periods of a sharp decrease in the selling price of copper, and it may be quite confidently predicted that it can serenely survive another, in case it should materialize.



GENERAL VIEW OF COLLINSVILLE

Collinsville Smelter of the Bartlesville Company

By E. H. LESLIE

The smelter of the Bartlesville Zinc Co., which is controlled by the American Metal Co. and is situated at Collinsville, Oklahoma, besides being one of the most modern American natural-gas smelters, is the largest zinc smelter in the United States. The smelter site adjoins the right-of-way of the Santa Fe lines and is one-half mile south of the town of Collinsville, Oklahoma. While metallurgically the plant conforms with the general practice throughout the natural-gas belt, the mechanical equipment and scope of operations marks this as one of the foremost of the natural-gas smelters.

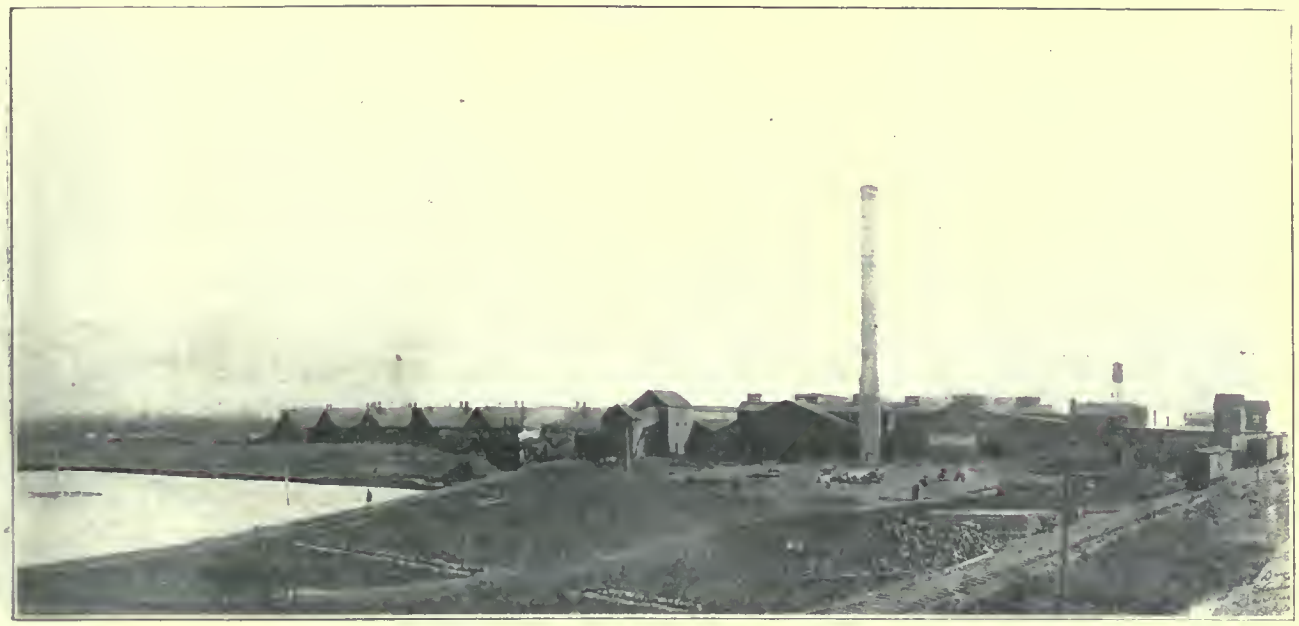
The buildings and equipment are characterized by an air of permanency in construction which contrasts strongly with the temporary look of the great majority of natural-gas smelters. Improved mechanical devices, an improved type of construction of the cellar distillation furnace, and a turbine power-plant, are some of the features which evidence a carefully engineered plant and would augur that it will be one of the last gas smelters to follow in the footsteps of those of Iola, Kansas, other conditions being equal.

The smelter site is ideal for the economic smelting and handling of smelter products. The topography is level, with a depression toward the south and at the rear of the furnaces, which affords dumping space for retort residues for years to come and also furnishes ground well adapted to the forming of roasting piles for the clinkering of retort residues from the Butte ores which are treated at this plant. The buildings are of frame and corrugated-iron structure, the general nature of which will be seen in the accompanying halftones. Turn-outs from the main tracks have been laid into the smelter grounds whereby standard-gage cars deliver the concentrate and smelter supplies and remove the smelter products.

Concentrate Treated

The concentrate, which is at the present time being treated, is derived largely from the mines of Butte, Montana, where it is obtained by a flotation process. The well known Joplin 'jack' together with other sulphide and carbonate concentrates from Colorado, Utah, California, and New Mexico are also treated. The different lots of concentrate as received at the plant are stored in separate bins provided for this purpose in the ore-house. The carbonate concentrate, which is derived largely from the mines of Colorado and New Mexico, upon arrival at the smelter is crushed in one of two crushing units, one of which is a Jeffrey hammer crusher and the other a jaw crusher. From the jaw-crusher unit the product is conducted to a trommel screen, the oversize from which is returned to a set of rolls. The combined product from this carbonate-crushing plant is elevated by a bucket-elevator to a belt-conveyor and thence taken to the carbonate storage bins.

The moisture contained in the Butte ores varies from 15 to 20% and is reduced in the dryers to from 4½ to 5% before being roasted. The Butte concentrate is drawn from the storage bins into cars and removed by hand to the dryer room, where it is dumped into the foot of an elevator which raises it to the feed hopper of the dryers. There are two circular dryers, each operated by a 40-hp. Westinghouse motor, and one large beehive dryer in the drying plant equipment. Circular



PLANT OF THE BARTLESVILLE ZINC COMPANY.

type dryers, which were developed in smelters at Iola, Kansas, have come to be standard equipment in the natural-gas smelting belt. The construction of these dryers is simple and their operation efficient. The hearth consists of a circular iron plate, about 12 ft. in diameter, which is heated with the natural gas from underneath. The concentrate is fed into the dryer through a hopper at the centre and moved over the plate to the periphery, by a set of revolving rabbles mounted on radiating arms, where it is discharged. In the ordinary type of circular dryer the hearth is covered with sheet iron, while in the beehive dryer the hearth is covered with a beehive-shaped brickwork. While the relative efficiency of these furnaces is doubtful, it would seem from a thermal standpoint that the beehive dryer presented points of vantage. The losses due to dust are inappreciable. The concentrate as discharged from the dryers is elevated to a 2-mesh screen, and the oversize is returned to a set of 24-in. rolls for re-crushing. Crushing after drying has come to be standard practice through the district. The dried concentrate, which passes two mesh, is then taken by means of a belt-conveyor to the circular steel feed-bins, which are superimposed and situated at the feed ends of the roasting kilns. These storage bins for the dried concentrate are 10 ft. diameter and 15 ft. high, and will store about 50 tons of concentrate each.

Roasting Furnaces

The roasting plant consists of six modified Cappeau furnaces. These furnaces are of the reverberatory type and are 175 ft. long. The hearth is 13 ft. between walls, and the furnaces have a capacity of from 25 to 30 tons per day. The Cappeau furnace is of the general Ropp type, from which the Cappeau and its modifications have sprung. The hearths are supported by columns to permit of the circulation of air underneath and a slotted opening in the centre of the hearth passing through the furnace allows the rabble arm, which is supported on a truck moving under the furnace, to pass through the furnace. The rabbling mechanism is both simple and efficient and consists of a series of plows mounted in rake fashion on a rabble arm. The rabble arm is mounted on an upright post supported on a four-wheel truck. The truck is drawn by a continuous cable passing around two large sheaves at each end of the furnace. When passing through the furnace the truck passes underneath the hearth and the upright post supporting the rabble arm passes through the slotted opening in the centre of the hearth. After passing through the furnace the truck and rabbles move around the large sheave wheel at the discharge end and back to the feed end of the furnace. The truck moves over an ordinary narrow-gage track and the rabbles are air-cooled during their passage outside of the furnace. The ends of the furnace are closed by iron doors which are hinged at the top and opened and closed by the passage of the rabble through the furnace. The truck with the rabbles is pulled through the furnace and returned by a continuous wire cable, which passes under the hearth and around the sheaves at the ends of the furnace. In the operation of these furnaces the rabbles pass over the hearth from 15 to 24 times per hour, depending upon operating conditions. The rabbling mechanisms of the six furnaces are driven by a 50-hp. motor which is belted to a line shaft from which connections are made with each of the furnaces.

The dried concentrate is fed automatically to the hearth of the furnace from the circular steel feed-bins previously mentioned, being dropped upon the feed end of the hearth through a feeder which is tripped by the passage of the rabbles through the furnace. The concentrate is discharged over grizzlies placed on the top of industrial cars into which the roasted product

POTTERY AND ROW OF DISTILLATION FURNACE

fails. Any clinker is thus removed and the concentrate is now ready for the mixing-room and retorts. The method of firing the furnaces is by natural gas and air introduced at intervals along the sides as in the Zellweger furnace.* The gas consumption per furnace amounts to about 250,000 cu. ft. per day. The greater efficiency claimed for this type of furnace over the Zellweger furnaces is due to the lower arch, better reverberatory effect, and a better enclosed and more compact structure. The furnaces at this plant are doing excellent work and reducing the sulphur in the concentrates treated to about one-half of one per cent.

The roasted product from the furnaces, which is discharged into the industrial cars, is trammed to a hydraulic elevator and the cars elevated and dumped into circular steel storage-bins. There are twelve of these bins, each being 20 ft. high and 14 ft. in diameter and having a capacity of about 150 tons.

The mixing-room is conveniently situated with reference to the roasted concentrate storage, carbonate, and fuel bins. The industrial tracks from the bins pass over scales in the mixing-room, where the different components of the charge are weighed and then dumped into a rotary drum concrete mixer. The fuel used consists of 'dead' coal from Pittsburg, Kansas, semi-anthracite from Arkansas, and coke breeze. The coal is crushed in a Jeffrey pulverizer. As the mixed charge which is ready for the retorts emerges from the mixer it is elevated by a bucket-elevator to a belt-conveyor and transferred to the steel charge-bins. The charge is drawn from the bottom of these bins into the steel charge-cars. Here it is slightly dampened as drawn from the bins to prevent dusting and facilitate handling. It is then removed by horses and delivered at the charge-floors of the distillation furnaces.

*'Zinc Smelting at Bartlesville, Oklahoma,' by E. H. Leslie, *Mining and Scientific Press*, July 11, 1914.

Distillation Furnaces

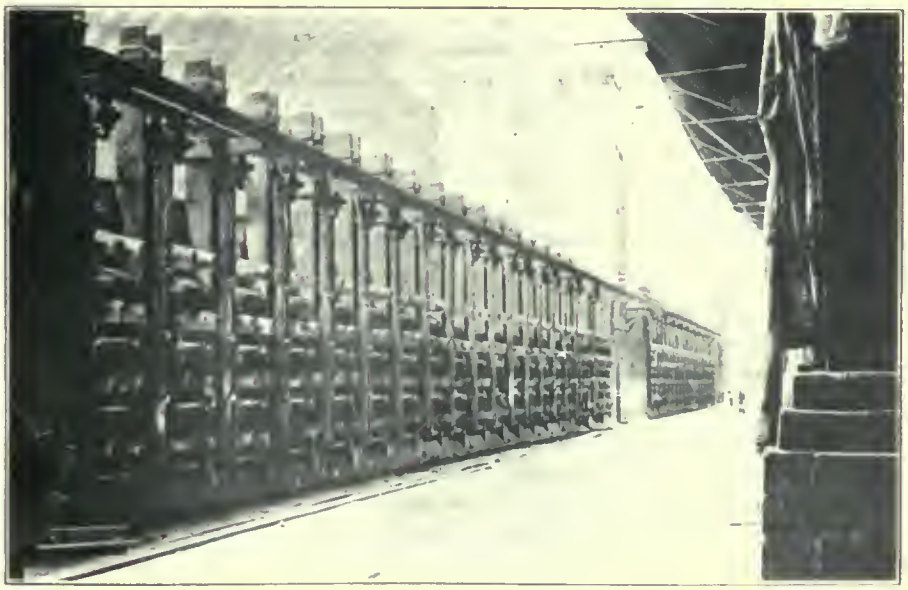
The retort furnaces, of which there are 12 blocks at this plant, are a new development in the district, and present several features which are noteworthy. The furnace blocks are separately housed in frame buildings with sheet-iron roofs, as shown in the halftones of the smelter, and are arranged in parallel as is the general practice in zinc smelting in the United States. An industrial track at the rear of the smelter buildings serves for the delivery of the retorts, condensers, and furnace supplies and for the removal of spelter. It will be seen that the furnaces are of the excavated cellar type, as is common with all the natural-gas furnaces throughout the region. The furnace floor is at ground level. The halftone presented shows an interior view of one of these smelter houses and furnishes a general idea as to the layout and construction of the retort furnaces. It will be seen that the furnaces are built in two separate stoves. Each stove has 10½ sections on a side, or 21 half-sections, and each half-section is made up of 8 retorts, these being arranged in 4 rows as shown. There are thus 336 retorts on one side of the block, or 672 retorts to the block, making the whole plant of 12 blocks comprise 8064 retorts. It will be seen that the furnace is braced with double buck-staves at each half-section, which gives a much more staple structure than the single buck-stave furnace. It is also to be noted that the furnace has an individual blow-box for the injection of the gas and air fuel mixture at each half-section, which has come to be recognized as the best practice. The furnace block is made up of two separate units with individual stacks and equipment. The advantages of this construction are in the furnaces' operation, the dual furnace block with the smaller units making a more flexible plant, and the smaller units are

BUILDINGS AT THE COLLINSVILLE SMELTER.

more wieldy and present structural superiority. The structural details are similar to those of the furnaces at the National Zinc Co.'s Bartlesville smelter.†

The air supply for nine blocks of these furnaces is conducted to the furnaces through one common air main. The air supplied is furnished by two fans connected with this main which are always in operation, and two others which are held in reserve to be used in case of emergency. The three other blocks of furnaces are each fitted with smaller individual blower fans, which is the theoretically proper arrangement. Each half of the furnace block is fitted with a water gauge, and the air pressure is regulated by the furnace fireman. The present practice seems to tend toward an individual blower for each block. The advantage of the individual blower arrangement for each block of furnaces is that when an increased amount of air is drawn from the main for use in one furnace, it does not decrease or cause a variation in the pressure on the other furnaces, as is liable to happen when one blower or fan is used to supply air for a number of blocks.

The retorts are charged by hand in the usual manner, and the metal is drawn three times a day. The drawing of the metal is done by moving the draw-car in front of the retorts, putting the pot in position by means of a hand winch, and collecting the spelter in the pot. The oxidized zinc or 'blue powder' is skimmed from the pot with a shovel and thrown upon the furnace floor, from which it is subsequently charged in the last two sections of the furnace, as is the usual custom. When the pot is full of spelter the draw-car is moved along the track to the molds and the spelter is cast into slabs of the usual weight and stored in a conveniently arranged yard for shipment.



COLLINSVILLE DISTILLATION FURNACE.

In cleaning the retorts, water under pressure is used, the water, of course, being converted into steam as it enters the retort. The residue blown out against the shield falls into the chutes in front of the furnace and thence into the cellar. Here it is collected in pans as shown in the foreground of the general view of this plant, and dragged by horses to the dump.

†'The National Zinc Company, Bartlesville,' by E. H. Leslie, *Mining and Scientific Press*, July 25, 1914.

Treatment of Residue

The residue from the Butte concentrate, which contains silver, is sintered in a similar manner to the practice at Bartlesville.‡ Such residues are removed from the furnace in industrial cars and subsequently clinkered in roasting heaps. The heaps as made at this plant are approximately 45 ft. square. A bed of residues 2 ft. thick is first spread out on the ground, the material being dumped into place from the cars which are brought to the clinkering ground on an elevated tramway. Upon this bed of residues the brickwork channels are then laid. A permanent lateral of brickwork is run across the centre of the bed from one side to the other. This lateral is covered with dirt to prevent the leakage of air through the brickwork. From this permanent lateral there are laid, at right angles to it and connected with it, branch channels on either side. These branch channels are constructed of brick with open interstices to allow the escape of air from them. When the brickwork has been completed and the permanent lateral banked with dirt, the residues are dumped on top and the pile is fired at the point near the permanent lateral. The air is then turned on and the combustion spreads to the limits of the pile. More residues are then added on top until the pile is completed. Smelting operations are on a larger scale at this plant than at Bartlesville No. 2, and a greater amount of silver-bearing residue produced. The clinkering operation of carbon reduction is conducted in somewhat larger heaps than at Bartlesville, but the principle and results obtained are identical. The air for combustion which escapes through the interstices of the brickwork of the channels is supplied by a fan blower, the air being distributed to the various heaps by a system of galvanized iron pipes. The silver-bearing clinker is shipped to the blast-furnaces for further reduction.

Pottery

The clay for pottery purposes is delivered at the pottery in standard freight cars and weathered out of doors for about two months. The pottery crushing equipment for crushing old retorts, adobes, and clay, consists of the standard jaw crusher, Jeffrey pulverizer, and screen, the oversize being returned and recrushed in the Jeffrey crusher. The retort mixture is made of about one-half adobes and one-half clay. The mixture is pugged, cut into convenient blocks, and stored for a few days. It is then re-pugged and molded by means of a hydraulic Mehler press into retorts. The pressure exerted by the press on the retorts is about 1000 lb. per square inch. The capacity of the plant is about 400 retorts per day.

As removed from the press, the retorts are taken to the drying-rooms, where they are kept for about 60 days and here completely dried by exhaust steam coils. They are then taken from the rooms as required for use at the furnaces on flat-bottom cars. At the furnaces the retorts are placed in the pre-heating ovens, which are rectangular in shape and at the rear of the furnace buildings, as shown in the illustration. One of these ovens is supplied for each two blocks of furnaces, and the retorts are kept in these ovens for 12 hours before being used in the furnaces. The condensers are made of one-half clay and one-half crushed old retorts, the material being pugged and the retorts molded in a retort machine. They are then crimped, dried, and burnt in kilns for use at the furnaces.

The power-plant is one of the most modern type. There are two gas-engine units which consist of two Westinghouse, internal-combustion, engines direct connected with two, 135-kw., alternating-current generators. These generators are 440-volt, 177-ampere machines, making 240 r.p.m. There are also three 100-kw. turbine sets. These sets are composed of a Curtis turbine direct-connected with a General Electric, alternating current, 100-kw. generator. These generators operate at 480 volts and 150 amperes rating. The boiler plant consists of three Heine safety boilers, two of which are 370 and one 250 horse-power.

The Collinsville smelter embodies many features which are not common with the other Oklahoma natural-gas smelters, and the beehive dryer, Cappeau type roasting furnaces, and double-stove distillation furnaces are being profitably operated under the management of E. G. Godshalk. The smelter presents a most economic practice in natural-gas smelting and gives promise of a spelter production for many years to come.

‡'Zinc Smelting at Bartlesville, Oklahoma,' by E. H. Leslie, *Mining and Scientific Press*, July 11, 1914.

Copper Production of Leading Mines

Copper production of some of the principal mines of the United States is as follows:

Mine.	1913.	Half of 1914.	Estimated for 1914.
Anaconda	241,983,323	124,700,000	249,400,000
Calumet & Arizona	52,987,383	33,257,000	66,000,000
Chino	50,511,661	35,000,000	70,000,000
East Butte	14,401,108	7,413,105	15,000,000
Granby	22,688,614	10,300,000	21,000,000
Greene Cananea	44,480,514	15,000,000	30,000,000
Miami	32,867,666	19,511,950	40,000,000
Nevada	64,972,829	29,920,399	60,000,000
North Butte	28,318,321	15,000,000	30,000,000
Old Dominion	30,293,253	17,879,000	35,000,000
Ray Consolidated	52,341,029	36,478,762	72,000,000
Shannon	18,793,724*	6,048,000	12,000,000
Shattuck-Arizona	13,219,756	7,514,198	15,000,000
Tennessee	13,493,140	7,800,000	15,000,000
Utah Consolidated	7,710,668	3,450,000	6,900,000
Utah Copper	113,942,834	72,865,023	145,000,000

*16 months ended December 31, 1913.

None of the Lake properties have been included, as the strike which continued up to the last of April interrupted production.

The Burma ruby mines, India, produced rubies worth $21,000 in June from washing 110,000 loads (16 cu. ft.) of gravel. Royalties payable were $4900.

Leaching Experiments on the Ajo Ores

By STUART CROASDALE

*Not long ago I was called upon to conduct some experiments on the treatment of ores from the New Cornelia copper mine, Ajo mountains, Arizona, for the Calumet & Arizona Copper Co. The problem was a very interesting one and contained some unusual features. Incidental to this problem was the utilization, if possible, of a large amount of low-grade pyrite in the Bisbee mines of the company.

The New Cornelia mine is 45 miles south of the Gila Bend, the nearest railroad point, on the Southern Pacific railroad, and about 160 miles, almost due west, from Tucson. The region is one of the most arid in the United States, and the normal annual precipitation, as given by the United States Weather Bureau covering a period from 1870 to 1901, is 3 to 5 inches. During June and July, 1913, the records kept by the Company gave the following results, showing the enormous evaporation that can be expected, which may be a factor in leaching operations on a large scale:

	High, °F.	Low, °F.	Average, °F.
June	112	62	84.0
July	115	71	87.8
Evaporation.		June.	July.
Concrete tank, inches		11.7	10.72
Iron tank, inches		14.8	13.07
Rainfall, inches		None	0.77
Cloudy days		None	10.00

Aside from several springs about 10 miles from the property, the nearest known water in quantity at the time these experiments were made, was the Gila river at Gila Bend, 45 miles distant. Part of the development of the property, of course, included drilling for water in the valley, which was in progress at the conclusion of my experiments.

The ore deposit itself is unusual. It consists of an intrusive plug of monzonite or granite porphyry. Chalcopyrite, bornite, and magnetite were finely disseminated throughout the magma in sufficient quantities to make the greater part of the mass commercial ore to a certain depth. Erosion has removed the surrounding country rock and left the plug sticking out at the base of the mountains as two or three cone-shaped buttes, without overburden of any description. Owing to the aridity of the country, there has been no leaching and no secondary enrichment. Instead of following the contour of the surface, as might be expected, the drill records (in the mine model) show oxidation to have taken place quite uniformly downward throughout the mass, and the division between the oxidized and sulphide ores is almost a horizontal plane. The transition zone between the oxidized and sulphide ores is also quite narrow—much narrower than would be expected.

The oxidized ores amount to about one-third of the total ore developed. The greater part of the copper exists as carbonate, although there is some silicate and some oxides, including cuprite. There is also a small amount of sulphide, as residual chalcopyrite and intermediate forms. The oxidized iron exists in both ferrous and ferric condition, both soluble in acid. While the chalcopyrite was very generally disseminated throughout the magma, there seems to have been a tendency for it to segregate in some portions, thus producing a higher-grade ore. The average grade of ore used for experimental purposes was placed between 1.5 and 2% copper. What the ultimate average grade will be will depend upon the cost of treatment.

Methods of Treatment

From the foregoing it will be readily seen that the conditions of the problem demand simplicity of process and large scale of operations. Of course, a railroad will be built to the mine, but whether the ore will be brought to water or water will be brought to the ore are factors yet to be considered and may have their bearing to a certain extent on the method of treatment adopted, when freight and fuel costs are estimated.

Methods of leaching with solutions of reducible salts, like ferric sulphate, ferric chloride, and cupric chloride, have some advantage in their solvent power on cuprite and chalcocite or other intermediate sulphides, but have little action on chalcopyrite. These salts are expensive and their value as commercial solvents depends upon their regeneration by some cheap method of oxidation after the dissolved copper has been precipitated. This difficulty has not yet been overcome, and the results from attempts to use these methods have been disappointing even in the hands of skilled metallurgists. The same may be said of sulphurous acid and ammonia processes. Two methods of treatment, however, are available, and both are entirely reliable and feasible under the conditions involved. One of these is the old Henderson process of roasting with salt, and the other is leaching the raw ore wtih sulphuric acid. A comparison of these two methods may be made briefly as follows:

By using the chloridizing roast, all ores on the property could be treated by the same process—oxidized, sulphide, and intermediate. This would mean the construction of only one plant. The average extraction of the copper would probably be higher than that obtained from acid leaching, and the small amount of silver in the ore would be recovered to a large extent. By mixing the ores, little if any sulphur would have

*Extract from a paper to be presented at the Salt Lake meeting of the American Institute of Mining Engineers and printed in the *Bulletin*, August 1914.

to be added as pyrite. The only chemicals required would be salt, to the extent of 5 to 10% of the ore treated, and possibly a small amount of pyrite. Both of these could be transported in ordinary freight cars. There would be less corrosive solutions to handle. There would be a minimum amount of iron and alumina passing into solution. There would be no appreciable absorption of copper by the slime.

On the other hand, this method would require dry crushing of the ore to 20 or 40 mesh, which would be troublesome if not prohibitive on the oxidized ores on account of the difficulty in controlling the poisonous dust, in addition to the expense of grinding. It would involve a roasting cost. It would mean a more expensive plant, and a more extensive plant for the same capacity, due to the slower percolation of the fine material, which would require a much larger vat area of less depth to hold the tonnage required. It would mean a supply of cheap salt. A chemical precipitant would probably have to be used to recover the copper.

Leaching with Sulphuric Acid

By leaching with sulphuric acid, the oxidized ore can be treated raw and need not be crushed finer than ½ in. or 2-mesh size, or perhaps coarser. Owing to the high oxidation of the surface ores and apparently small zone of partly oxidized ores, a large tonnage can be expected to give a comparatively high extraction by this method. Sulphuric acid can be made as a by-product at the roasting plant of the Calumet & Arizona company at Douglas, or if the calcines are converted into sponge iron and used as a precipitant for copper, the low-grade pyrite from Bisbee can be cheaply transported and acid made at the mine. If electrolytic precipitation can be used, a small percentage of the acid consumed can be regenerated. This method of extraction will permit of less expensive plant construction for the oxidized ores.

On the other hand, sulphuric acid alone will extract none of the copper existing as sulphide, only half of the copper existing as cuprite, and may be indifferent toward the silicate of copper. It will extract none of the precious metals. Owing to the character of the oxidation of the ore, already mentioned, considerable iron and alumina pass into solution as readily as the copper, which will seriously interfere with any form of electrolytic precipitation and render the amount of acid regenerated a doubtful asset when compared with the amount consumed. As an offset to this objection, some of the iron is in the ferric condition, which assists materially in the solution of the minerals mentioned above.

If acid is made at Douglas, it will have to be transported several hundred miles in tank cars, which will have to be returned empty. If acid is made at the mine from low-grade pyrite, a gain will be made in transportation, but the cost of an acid plant will be added to the cost of the leaching plant, and the calcines will have to be utilized. Almost an entirely new plant will have to be constructed for treatment of the intermediate and sulphide ores. The problem is clearly one in arithmetic as well as metallurgy, so laboratory experiments were made on both methods.

Leaching Experiments

These were made only on the raw oxidized ores. The crushing varied from 8 to 2-mesh sizes. The experiments were conducted in glass and stoneware jars provided with small air-lift pumps for circulating the lixiviants. Both standing and circulating lixiviants were tested. The strength of acid solution varied from 3%, or just enough to dissolve the copper in the ore, up to a 10% solution. Sulphuric acid was used. All references to this acid mean 100% H_2SO_4 and not commercial acid. Only enough lixiviant was used in each experiment to cover the ore. The results were as follows on 24-hr. treatment:

8-Mesh Ore

	Standing lixiviant		Circulating lixiviant	
Acid in lixiviant, %	Cu extracted, %	Lb. acid used per lb. Cu dissolved.	Cu extracted, %	Lb. acid used per lb. Cu dissolved.
3.0	46.8	3.2	48.7	3.3
4.0	54.7	3.3	71.0	2.7
4.7	56.1	2.8	85.2	3.2
10.0	81.8	2.8	88.6	3.5
	4-Mesh Ore			
3.0	42.9	2.4	70.4	2.0
4.0	44.3	2.4	74.4	2.3
4.7	48.3	2.3	82.3	2.4
6.3	58.2	2.3	80.8	2.8
10.0	78.4	2.2	85.7	2.8

These experiments showed that circulating the lixiviant increased the extraction of copper without seriously increasing the consumption of acid; that crushing to 8 mesh increased the consumption of acid without materially increasing the extraction of copper; and that increasing the strength of the lixiviant increased the extraction of copper and also the consumption of acid when the lixiviant was circulated through the ore. The fine ore produced in crushing to 8 mesh seriously interfered with the percolation of solutions. Further experiments were made on 4-mesh material by increasing the time of leaching, with the following results:

	5% acid lixiviant		10% acid lixiviant	
Time of leaching, hr.	Cu extracted, %	Lb. acid used per lb. Cu dissolved.	Cu extracted, %	Lb. acid used per lb. Cu dissolved.
24	82.3	2.4	85.7	2.8
48	83.7	2.6	90.1	2.6
72	84.2	2.7	87.6	4.2
96	86.7	..	89.1	4.0

Additional time with 5% acid lixiviant increased the extraction very slowly—probably from the fact that the acid was nearly neutralized. The 10% acid lixiviant always had plenty of free acid remaining after the copper was all dissolved. By referring to the analysis of this ore, it will be seen that the copper soluble in 10% sulphuric acid solution is only 90.6% when the sample is crushed to pass 100-mesh screen, so that a 10% acid lixiviant on a 4-mesh material for 48 hr. extracted about

all of the copper that could be expected. The above experiment was repeated on ore crushed to pass ½-in. or 2-mesh screen. Only a 10% acid lixiviant was used. The results, given below, were as good as those obtained from finer crushing:

Time of leaching.	Extracted, %
48 hr. without change of lixiviant	86.0
48 hr. Lixiviant changed after 24 hr.	87.5
72 hr. Lixiviant changed after 48 hr.	90.0
96 hr. Lixiviant changed after 48 hr.	87.0

As already stated, the oxidized ore contained some cuprite. When clean sulphuric acid is added to this mineral, one-half the copper is set free in metallic condition, remaining insoluble in the acid. As nearly as could be determined by averaging a number of analyses, the amount of copper thus set free was about 0.2% of the ore, or say 10% of the total copper.

Analyses of the lixiviants from a number of leaching experiments showed that a certain amount of iron passed into solution simultaneously with the copper. This averaged from one-third to one-half of the amount of copper in solution, or from 0.8 to 1.1% of the solution. Sometimes, with high iron and much kaolinized ores, it amounted to more than this. The iron was about equally divided as ferric and ferrous sulphates. Using 10% acid, the lixiviant passing from a charge of leached ore contained from 4 to 6% free acid in addition to the copper, iron, and alumina.

This combination of circumstances enabled me to use the partly neutralized lixiviant from a leached charge of ore for the first lixiviant on a new charge of ore and thereby not only neutralize the free acid in the lixiviant and at the same time enrich it in copper, but have a solvent for the cuprite (or metallic copper if formed) in the form of ferric sulphate. Since ferric sulphate was always present and the lixiviants were always circulated, it is scarcely possible that any cuprite could escape solution. As soon as the first lixiviant was neutral, it was sent to the precipitating vats. If it was left on the ore beyond the neutral point, some of the copper was reprecipitated in the ore. A new 10% acid lixiviant followed the first and finished leaching the ore, which in turn was neutralized on a new charge of ore.

[The laboratory experiments with chloridizing roasting gave results which did not indicate the advisability of large-scale experiments by that method. For the large-scale experiments on leaching the raw ore, five vats were constructed. A series of tests, utilizing in all 300 tons of ore, were made along the lines indicated above. Reference should be made to the original paper for the details of these tests; the summary follows.]

Summary of Operations

The average grade of this entire quantity of ore was much lower than anticipated and lower than that used for the laboratory experiments. All of the ore treated passed through a 2-mesh screen except the oversize from Test 1, which amounted to 9818 lb. This oversize ranged between 0.5 and 1 inch in size and was treated by itself as a special experiment to conform more closely to the practice of the Arizona Copper Co. at Clifton.

Analysis of a composite sample of the five lots of ore treated gave the following results:

	Calculated from 5 samples, %	Composite sample, %		Calculated from 5 samples, %	Composite sample, %
SiO_2	64.27	63.29	Cu, total	1.44	1.45
Fe	4.18	4.20	Cu, sol. in 10%:		
Al_2O_3	14.73	14.30	H_2SO_4	1.31	1.32
CaO, sol. in acid.	0.63	0.90	CO_2	1.30	1.26
MgO	...	0.80		Oz.	Oz.
MnO	...	0.14	Au	0.01	0.01
S, total	0.32	0.27	Ag	0.18	0.18
S, as sulphate	0.05	0.10			

The first charge was leached only 20 hr. and gave an extraction of 51.7%. The second charge was leached 39 hr. and gave an extraction of 71%, making an average leaching time of about 30 hr. and yielding an average extraction of 61.3%. If the time of leaching had been prolonged to 70 hr., corresponding to that of the 2-mesh material, the extraction of the whole lot would undoubtedly have been as good as that of the 2-mesh material alone. Therefore in all probability the ore can be leached successfully if not crushed finer than will pass a 0.75-in. screen.

The ore in Test 3, on the other hand, nearly all passed a 4-mesh screen. The fine material produced in crushing to this size very seriously interfered with the percolation of the lixiviants, and washing the ore; consequently it caused loss of time and gave low extractions. Had the entire quantity of ore treated been thoroughly mixed and crushed to a uniform size, the results would have been better than the average of the results obtained by treating each lot separately, so the average results given below are probably not the best obtainable and are certainly on the safe side.

Ore Treatment at the Junction Mine, New Zealand

This property is next to the Waihi mine, and the annual report for 1913 contains the following notes on mill work, as given by the mill superintendent, J. R. Noble: An average of 36.44 stamps out of a possible 40, worked and crushed 9.2 tons each per day. Screen analyses of stamp pulp was as follows:

Mesh.	Per cent.	Mesh.	Per cent.
+ 5	6.1	+ 80	4.1
+ 10	19.1	+ 100	3.2
+ 20	18.3	+ 150	4.0
+ 40	14.0	+ 200	3.0
+ 60	7.6	— 200	20.6

There were 9.4 tube-mills, out of 10, at work. Fineness of the ore after stamps and tube-mills averaged 1.3% on 100, 5.2% on 150, and 11% on 200 mesh, and 82.5% through 200 mesh. From this product was separated 17,151 tons of sand, of which 4.5% remained on 100, 21.6% on 150, and 33% on 200 mesh, and 40.9% passed through 200 mesh. Although fine, the sand percolated rapidly, thoroughly, and at a low cost compared with vacuum-filter treatment. Cost of tube-mills pebbles was 1.7c., and renewal of liners 1.84c. per ton of ore milled. Cyanide solution strength was 0.07% available, and the consumption was 1.25 lb. per ton of ore.

Recovery of 89.9% of gold and 74.1% of silver from 98,383 tons of ore was done at the following cost:

	Per ton.		Per ton.
Rock-crusher	$0.12	Precipitation and clean up	$0.09
Stamps	0.22	Assaying (985+samples)	0.04
Tube-mills	0.34	General	0.14
Concentrators	0.09		
Percolation and vacuum-filter	0.66	Total	$1.70

Operations of the Tigre Mill

This plant is situated in the district of Moctezuma, Sonora, Mexico, and produced the following results in 1913, according to the report of the general manager, L. R. Budrow: The 20 stamps worked 91.7% of the time and crushed 67,037 tons of ore. An 8-ft. Hardinge mill was installed, increasing the capacity of the stamps from 4 to 11 tons per stamp-day. Additional cone-bottom thickeners, Wilfley sand and Deister slime tables are treating the full tonnage. Treatment of the ore presents several difficulties, concentration with subsequent dewatering being necessary or cyanide consumption becoming excessive. Even after concentration the ore still contains 3.4 lb. copper per ton. Cyanidation was materially improved in 1913 by heating solutions, the extraction of silver being higher and cyanide consumption lower than formerly. Good results and economies have been effected in lower cyanide consumption, and by removing the excess of copper from the solutions. Copper-bearing ores are now treated satisfactorily. Total recovery at the mill and cyanide plant was 92.8%, at the following cost per ton:

Stamp-mill.		Classification, elevating, dewatering	$0.217
Crushing	$0.330	Treatment	$1.728
Regrinding	0.176	Filtration	0.242
Concentrating	0.415	Precipitation	0.202
Alterations	0.002	Melting	0.239
Total for 56,511 tons	$0.923	Dam and re-treatment	0.061
Cyanide plant.		Experimental	0.028
Conveying and screening old tailing	$0.120	Alterations	0.002
Tube-milling	0.540	Total for 86,536 tons	$3.379

IMPORTS of brown coal, coke, hard coal, and briquettes into Hungary in 1913, amounted to 5,200,000 tons, against 4,870,000 tons in 1912. The output of Hungarian coal mines was 10,568,000. The government owned coal mines are worked at a loss, the estimate for 1914 being $300,000. Coal deposits of the country are estimated to contain 350,000,000 tons in sight, also available 1,358,000,000 tons.

SAND AND GRAVEL OUTPUT of the United States in 1913 was 25,367,060 and 54,087,429 tons, worth a total of $24,165,837. The increase over 1912 was 11,099,928 tons and $1,052,629. Glass sand output was 1,791,800, worth about $1 per ton.

Sanitation Work at Cuban Iron Mines

By CHARLES F. RAND

In the conduct of mining operations in Cuba careful attention to the health conditions of employees is necessary at all times. As is well known, the elimination of mosquitoes and flies is of first importance in the prevention of tropical diseases. When the Spanish-American Iron Co. began its operations in Cuba (see accompanying map) mosquitoes were a source of great annoy-

ance, and the examining engineer who first visited Diaquiri reported that the sound of the mosquitoes in his room at night was not unlike the noise made by a swarm of bees. Similarly, at Mayari our consulting engineer was driven out by mosquitoes from what is now the site of the town of Felton, and included in his report a recommendation that provision be made for quartering the men on houseboats during the construction period, fearing that through the resulting loss of sleep and sickness the efficiency of the laborers would otherwise be very low. This was not found necessary, however, as the low spots were filled while dredging the harbor, the mangroves were cut away all around the island, and the necessary preventive precautions taken throughout the vicinity. The resultant effect is shown by the fact that for years mosquito nets over beds have been unnecessary both at Daiquiri and Felton.

During 1908 there was yellow fever in Daiquiri. It was brought there by a man not in the employ of the Company. In combatting this, the government sanitary department, under the direction of the medical corps of the U. S. Army of Occupation, thoroughly disinfected and cleaned all the mining camps. Since that time scientific extermination of mosquitoes has prevailed and all these places have been kept clean, with the result that the mosquito has almost entirely disappeared. The reduction of malaria at Daiquiri due to the absence of the mosquito is shown by the following table:

Year.	Av. men on payroll.	Total cases of malaria.	Per cent.
1907	1315	689	52.0
1908	1292	632	49.0
1909	1391	234	17.0
1910	1448	142	10.0
1911	1480	186	13.0
1912	1294	53	4.0
1913	1301	68	5.0
1914 (first 3 months)	923	3	0.3

The system used for the extermination of the mosquito is as follows: (1) the gathering up of containers that are capable of holding water, such as cans and bottles; (2) the screening of water barrels and other vessels necessary for domestic or other uses; (3) the draining of pools and ditches; (4) the use of petroleum where drainage is not practicable; (5) into large water tanks that cannot be screened to advantage, small fish of the minnow species are put, to destroy the larvae. Attention is also paid to the general sanitary condition of the camps. All garbage, manure from stables, and sweep-

BUILDINGS COVERED WITH CANVAS WHILE BEING FUMIGATED WITH SULPHUR.

SITE FOR PLAYGROUND IN LABORERS' VILLAGE, FELTON, CUBA.

ings from the roads are gathered and burned daily. Out-closets are limed at frequent intervals.

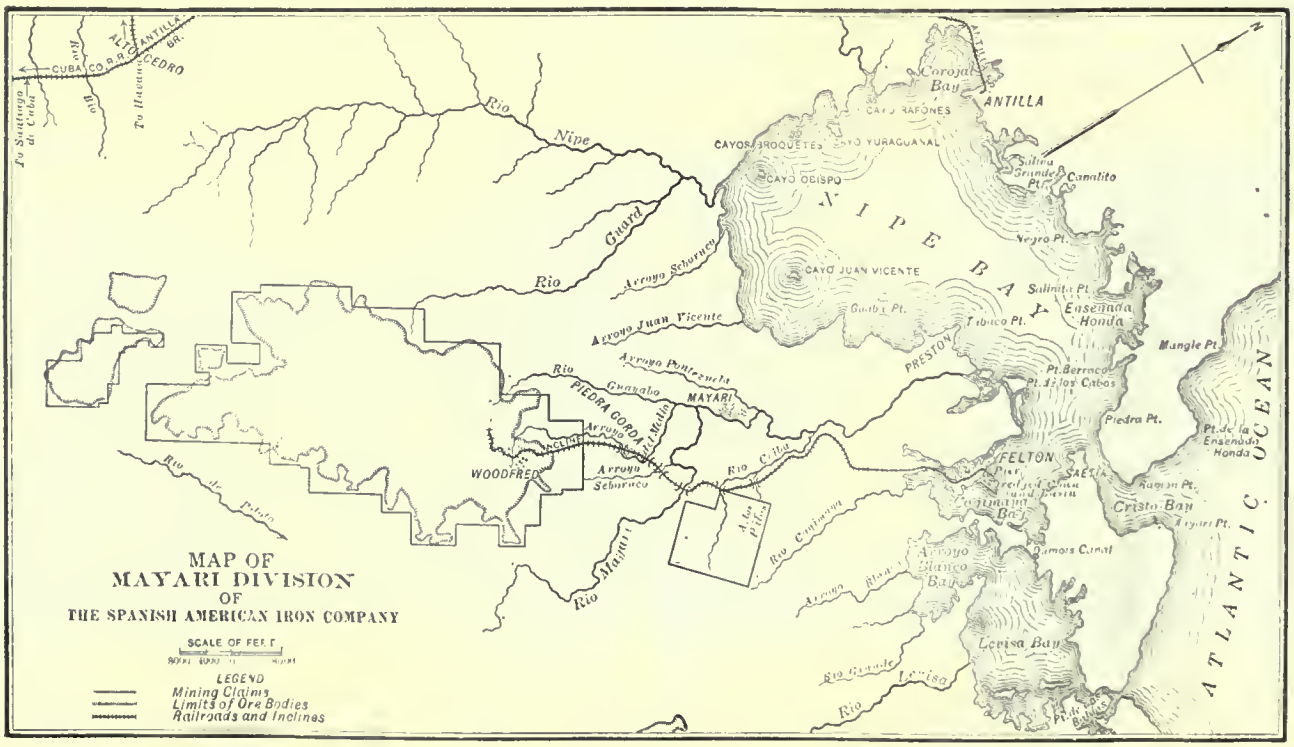
The following translation of a circular issued to its employees by the Spanish-American Iron Co., Cuba, will serve to illustrate the methods pursued to prevent the growth of mosquitoes. Similar circulars regarding flies are issued, and every effort is made to spread correct information about disease prevention.

The Mosquito

There are more than one hundred kinds of mosquitoes.

Mosquitoes breed only in water. They can breed in any kind of standing water which does not contain matter which is destructive to them.

Mosquitoes generally require from one to three weeks to develop; it takes less time in hot weather than in cold



weather. The female, three days after being hatched, lays her eggs, but in some cases more time elapses. Some species of mosquitoes lay from 300 to 400 eggs at a time. Some lay only one.

These are mosquitoes that live several months (as has been proved by hothouse processes or in other ways), but it is probable that few live more than one month.

Mosquitoes do not breed in grass, but they do breed in mud puddles, such places being the favorite haunts of the adults. Lichens contain a sufficient amount of water to breed a rare and small species of mosquito.

The different kinds of mosquitoes have, also, different habits, just as different kinds of birds, flies, etc.; some are domestic, some are found only in woods, and some are migratory.

Some of the domestic mosquitoes breed in clean water, fly a short distance, and usually enter the houses. The majority of migratory mosquitoes breed in salt marshes and fly long distances. They do not transmit malaria.

Careful proofs, direct as well as eliminative, have demonstrated that certain kinds of mosquitoes are the only known means of transmitting malaria and yellow fever. It is known that other diseases are carried by the mosquito.

Of the domestic variety, the dangerous, malaria-carrying mosquitoes (several kinds of the species *Anopheles*) are the most widely distributed. These fly to a distance of only about 500 yards.

One of the most common and most dangerous mosquitoes in the tropics is the *Stegomya fasciata*, which is the true carrier of yellow fever.

It is well known that mosquitoes inoculate more than once, as can be learned from observation and proved by the transmission of disease from one infected person to another.

The mosquito is an unnecessary and dangerous plague. Its propagation can be avoided by such means as drainage, the filling of swamps, changing waters, emptying or covering all receptables for water, sprinkling oil on all stagnant waters when other remedies are impracticable. Much care must be taken with water tanks, house vessels, pools, cisterns, gutters, old cans, holes in trees, swamps, and wells. Since malaria-carrying mosquitoes can breed in springs, their banks should always be kept clean, and *guayacones* (a small fish similar to the minnow) should be placed in them.

The broods of insect-devouring birds should be protected. All receptacles for water should be carefully covered to keep out mosquitoes in order to prevent the propagation of malaria and yellow fever.

The development of any species of mosquito which has a tendency to threaten the life and public health, therefore, is the result of carelessness or ignorance.

The malaria-carrying mosquito does not sting in the daytime. It comes out at sunset, and all night long works actively.

Everyone ought to protect himself against the malaria-carrying mosquito by sleeping under a mosquito-netting.

Keeping the Towns Clean

In addition to the elimination of mosquitoes and flies, every attention is given by the foremen and by the sanitary force to maintaining cleanliness and order among the employees as well as around the dwelling houses and

SWIMMING POOL AT DAIQUIRI

in other parts of the towns. Even the most modest dwelling is supplied with a shower bath. A lavatory building with ample shower bath facilities is provided for single men living in the *barracons*. The machine shops has a modern lavatory, also individual metal lockers for clothing form a part of the *barracon* equipment. Each *barracon*, and lavatory, is in charge of an attendant who is held responsible for its sanitary condition.

The siphon condenser at the electric power plant at Felton draws its injection water from the bay and discharges into a 36-in. pipe which forms the main artery of the sewer system. This provides constant and abundant flushing of the sewers and prevents any possibility of stagnation. The outlet of the sewers is carried out to deep water in the *estero* at the rear of the island where there is a strong tidal flow. I have been close to the outlet in a row-boat during both low and high tide on a quiet day and found absolutely no odors. At Woodfred all sewers from the laborers' village are brought together in a sewerage disposal plant in order to avoid any possible contamination of the streams originating in the ore. This plant efficiently takes care of all waste.

Regular inspections are made of the dwelling houses and hotels, and daily inspection of laborers' quarters, hospital, lavatories, butcher shop, and bakery. A daily report is made by the Sanitary Inspector. Any defects in the sewer system or unsanitary conditions are reported by the inspector and means taken immediately to remedy the trouble. Monthly medical reports are also made. Each Saturday, oil and lime are put into the privies connected with the dwellings in the laborers' village where water closets are not supplied. When a laborer's house is vacated it is thoroughly fumigated and cleaned by the sanitary gang.

MONTHLY REPORT FORM.

Some time ago it was discovered that the milk supply of one of our villages was being adulterated by *pasta de boniato*, a paste made by grinding up dried sweet potatoes, and of corn starch. This discovery was made after a number of cases of fever among children were reported. To avoid this and insure suitable milk supply, the milk is tested each morning before being distributed. Both Daiquiri and Felton have efficient ice plants. Ice is sold to all families who wish it, at a low price. Also each labor gang is furnished free each day with a sufficient supply of ice for cooling the drinking water supply.

An abundant supply of good water is provided for all dwellings. The Daiquiri water supply comes from a point high up on an adjoining mountain above all dwellings. The Woodfred supply is taken from a small stream originating in the ore where there is absolutely no possibility of pollution. This supply is really remarkable for its purity. Felton water is piped twelve miles from the Mayari river, at a point above which there is only a scattered population. No sickness has ever been traced to the water supply.

Perhaps the most significant fact in showing the satisfactory sanitary conditions of Felton is the size of the present hospital and the number of patients treated as compared with the provisions made originally for taking care of sickness. Based on the experience of other corporations operating in that neighborhood, a large and well appointed hospital was built at Woodfred with the idea that the high elevation and the naturally healthy site would be advantageous in properly taking care of fever cases, the number of which it was expected would be large. After starting, however, these cases proved to be so few that the number of attendants was as a rule

Medical Department.

DAILY REPORT FORM.

greater than the number of patients; and a short time ago this large hospital was closed and the small emergency hospital at Felton was made the main headquarters of the medical department.

As Felton is in the centre of a large and prosperous sugar district, many men come to the mine from the sugar companies after the cane-cutting season is over. It has been demonstrated very often that the majority of the fever cases are brought by such recruits. At Daiquiri, the new men as a rule come direct from the north of Spain, and are not so likely to transmit fever. Notwithstanding the above mentioned facts, the proportion of sickness at the Mayari mines is extremely low, as shown by the following list, which does not include patients treated for injuries.

	1910.	1911.	1912.	1913.	1914, 4 mo.
Average number of men on payroll per month	729	736	691	757	415
Total sick cases per year	212	189	138	116	9
Average sick cases, per month	17.66	15.75	11.50	9.66	3
Percentage of sick	2.42	2.14	1.67	1.27	0.70

During the past year there were an unusual number of fever cases owing to the fact that a larger number than usual were employed on the railroad on account of reconstruction work. To this a great number of new men were employed. It might be well to speak in this connection of the ever present enemies, the *jejenes* (no see 'ems), which though not a carrier of disease so far as known, are nevertheless a troublesome pest. These will undoubtedly be eliminated sooner or later, but at present no satisfactory means of extermination has been proposed.

Quicksilver Production of the United States

The quicksilver industry of the United States broke a record last year, but not an enviable one, for with the exception of that of 1908, the production last year was the lowest since 1860. Final figures from every producing district, according to H. D. McCaskey, of the U. S. Geological Survey, give a domestic output of quicksilver for 1913 of 20,213 flasks of 75 lb. each, valued at $813,171, against a production of 25,064 flasks, valued at $1,053,941, in 1912. The decline was due partly to the large foreign output for the past few years, a dull market, and a general lowering of prices. Producers report 154,033 short tons of ore mined and available for treatment in 1913, against 166,564 tons in 1912, and the reduction of 136,278 tons against 155,693 tons in 1912. California, as usual, was the largest producer in 1913, with 15,591 flasks, valued at $627,228, a decrease from the output of 1912 of 4933 flasks in quantity and of $235,806 in value. The total value of the production of quicksilver in the state from 1850, the date of the earliest output, to the end of 1913 has been $95,902,923. The quicksilver output of Nevada in 1913 was 1645 flasks, valued at $66,178. The most important producer of quicksilver in the United States is the famous New Almaden mine, of Santa Clara county, California, which contains over 100 miles of underground workings, and which has produced steadily since 1850.

GOLD PRODUCTION of some West African mines in June was as follows:

Mine.	Tons.	Yield.	Profit.
Abontiakoon	11,017	£24,233	£10,232
Ashanti	9,112	37,216	.....
Broomassie	3,774	13,763	3,525
Taquah M. & E.	5,710	16,904	5,817

Short Tube-Mills

By H. W. HARDINGE

In the *Mining and Scientific Press* and other technical publications there have appeared of late several articles bearing directly upon the probable effect of increasing the diameter and shortening the lengths of pebble-mills. Many allusions have been made to the effect that the Hardinge conical mill has been the forerunner of the innovation. This we must grant is the case, but the effect of the cone on the short mill must not be overlooked any more than the application of the electric current to the motor or the steam to the engine, in order to make these devices serve the purpose for which they are intended. Competitors, but not users, have referred to the cone as addenda of questionable value, and one theorist has suggested a mill of 8 ft. diameter and 3 ft. length to correspond to the cylinder length of the 8 ft. by 36-in. Hardinge mill. Favorable preliminary tests are now being conducted in a Hardinge mill 10 ft. in diameter.

The term 'short' as applied to the tube-mill is relative. In most instances the comparison is made with reference to the standard tube-mills of 20 or more feet in length and of about five feet in diameter, hence a mill of 16 ft. or less is now termed 'short.' The original 'discovery' and use of the short mill is really older than the experience of some of the inventors.

My first experience with short tube-mills was in the construction and operation of one of 8 ft. in length by 6 ft. in diameter in 1903, and another 6 by 6 ft. in 1905. This latter mill was really the progenitor of the conical mill, for it was later lined with fluted cast iron plates forming cones within the mill, in a similar manner to the lining recently placed within a more modern 'short' tube-mill, the dimensions of which were originally 7 by 12 ft. Fig. 1 shows the 6 by 6-ft. mill above mentioned, and Fig. 2 the lining which was fitted within this mill and formed the first working conical mill. Thus a short tube-mill was still further shortened by having its length reduced to a mere surface, forming the base of two cones—if such surface can be considered under the term of length.

As one writer has recently remarked, there must be some critical length for a short tube-mill. In my opinion no exact length can be established owing to the fact that length and diameter must vary in direct relation to size and quality of feed. A very hard ore requires a diameter proportioned to the hardness and necessity for an impactive blow, which likewise applies to coarseness of feed. Lately attention has been directed to one of the innovations in the form of a short tube-mill having the dimensions of 8 ft. in diameter and 6 ft. in length. This excessive diameter (for length) has proved a failure. The mill has been converted into an internal dimension of 6 ft. by filling in the interior of the mill, and our last information is that it is doing better work. The mill with the original dimension was operated on fine jig tailing, the coarse uncrushed feed traveled across the 6 ft. in length without being crushed, and the mill became choked. This choking, however, is liable to occur with any form of pebble-mill when overfed. It was trouble of this character and the necessity of operating a choked mill for periods of several hours before grinding could take place, owing to a 'floating' of the pebbles in the uncrushed mass, that led to the conversion of the 1905, 6 by 6-ft., tube-mill into a conical mill, producing the same result with a reduction of power. When a conical mill is overfed and choking ensues, all that is necessary is to cut off

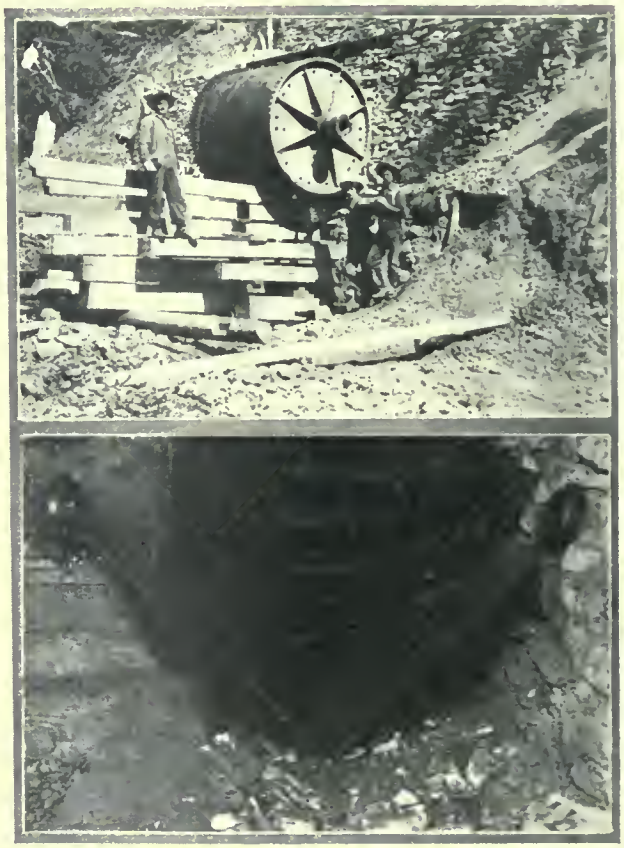

FIG. 1. ORIGINAL 6 BY 6 MILL USED AT CRYSTAL, COLORADO, IN 1905.
FIG. 2. LINING OF FLUTED CAST IRON PLATES.

the feed for a few minutes, when, owing to natural physical migration, the excess of feed is discharged by the crowding and displacing action of the pebbles in the largest diameter. As one millman expressed it, "indigestion is rectified by the mill immediately 'coughing up' its undigested feed." If the feed has assumed the relation of small pebbles of ½ in. or more in size, as has several times occurred in the course of our experience, these excessive sized particles must be removed before normal conditions will obtain, as they become practically a part of the pebble charge, too small and too numerous to be effective.

Referring again to the 'critical length' of a tube-mill, it is my belief that the length should at least exceed the diameter. One writer on this subject has suggested that lengths of 2, 3, or 4 ft. by 8 ft. diameter are pos-

sible. This idea probably emanates from the fact that these dimensions exist in the conical mill—cylindrical length only—while the diameter is 8 ft., and the total length, including cones, is about 12 ft. It is necessary to remember, however, that the diameter is constantly diminishing in fairly direct relation to the mass and size of crushing bodies, as well as size of particles undergoing division performing step reduction. In cylindrical tube-mill construction, designers either do not recognize or ignore the fact that physical laws for adjusting cause to effect must be obeyed. Many circuitous routes are often traveled to reach a point or end. The one in which the metallurgist is interested is that which will produce the greatest economic result. This particularly applies to the pebble-mill wherein forces should be graded to work performed. One would naturally use a sledge-hammer upon a spike and a tack-hammer upon a tack. Then why use an 8-ft. mill-force alike upon a 4-mesh particle and a 20-mesh particle, when the crushing force requirements vary as the cubes of their diameters, or, in the above mentioned division, 1:125? It is true that a short mill of 2 or 3 ft. in length by 8 ft. in diameter might fit the 4-mesh energy requirement, but should its employment be continued on the subsequent 10, 20, or 100-mesh particles returned as oversize for still further reduction? In the cylindrical mill this misapplication of force is necessary, is recognized by the metallurgist, at least to the extent that he is seeking a 'critical length'. In the matter of his crusher, or roll, he is not long in doubt. He adjusts the size to his requirement, possibly because he realizes, by physical observation, the reason for this mechanical adjustment. None the less, the same law should govern his finer divisions, when their relations, instead of being two, four, or eight to one, suddenly jump to hundreds to one.

THE BUREAU OF STANDARDS, Washington, D. C., has been working for some time on safety rules to be observed in the operation and maintenance of electric generating stations and sub-stations, and on the overhead and underground distributing wires in connection therewith, and a set of rules has been prepared for publication by the Bureau. In this work a large number of operating companies have been consulted, workmen actively engaged in the different lines of work covered by the rules, as well as state industrial and public-service commissions. The rules have been formulated so as to be complete and simple, and as easily understood as possible. These rules have been highly commended by a number of competent critics.

MEN EMPLOYED in quarries in the United States numbered 113,105 in 1912, of whom 213 were killed, or 1.88 per 1000 employed. Over 66% of these accidents are about equally divided among falls of quarry material, explosives, and haulage. The value of all quarry products was $78,284,572. The accident rate in France and Great Britain was 1.08 and 1.04 per 1000 employed.

The Norman-Federal Suit

In the Supreme Court of New York, Mr. Justice Philbin rendered the following (in part) opinion after hearing this suit:

This is a derivative action brought by the plaintiffs, Sidney Norman and others, for themselves and other stockholders of the defendant Federal Mining & Smelting Co., a corporation organized under the laws of Delaware (hereinafter called the Federal company), to procure a judgment declaring wholly void an agreement dated October 16, 1905, entered into between it and the defendant American Smelting & Refining Co. (hereinafter called the Smelting company), and requiring the Smelting company to account to the Federal company for the difference between the prices which it had paid for ores, slime, and concentrate delivered under the contract and the market price thereof. There was also joined as defendants the directors of the Federal company individually. The complaint against them was, however, dismissed without costs, upon the trial, and they are no longer in the action.

The contract complained of was an extension of one that had been made two years before, and which was practically upon the same terms. No question has ever been raised as to the propriety or fairness of the first contract. The second contract recited that it was the desire of the Federal company to sell, and of the Smelting company to buy, all of the lead-silver ores, etc., that might be produced from the properties owned or leased by the Federal company for a further period to begin on the day of the expiration of the contract then in force between the two Companies, and to end on August 31, 1930. By the stipulations of this new contract the Federal company agreed to sell all its ores, etc., to the Smelting company during such period. The prices at which such sales were to be made were the same as those mentioned in the contract of 1903, that is to say, for 90% of the lead contents of such ores, 90% of the average price in New York City; for common desilverized lead in lots of fifty tons or more, so long as the selling price should be $4.10 per 100 lb. or under, and when such selling price should exceed $4.10, then 90% of $4.10, plus one-half of the excess over $4.10. The new contract further contained substantially all the other provisions of the then existing contract of 1903, including the provisions authorizing the Smelting company to deduct the freight thereon to Denver or Pueblo, though shipment and delivery should be made to the Smelting company at any other point. It contained, among other things, an additional provision giving to the Smelting company the right to designate deliveries "to any smelting works wherever located and whether said smelting works shall be owned by the Smelting company or by any other persons." A provision requiring the Federal company to deliver to the Smelting company not less than 72,000 tons per year of ore, slime, and concentrate was also omitted. It was not established

that any of the terms of the contract were unfair or disadvantageous to the Federal company, or that there was any detriment because of it suffered by the company. With the exception of two minor differences above referred to and its duration, the contract in question is similar to the one made in the year 1903, when the board of directors were entirely independent and apparently fully competent to protect the interests of said Company. The contract of 1903 terminated in the year 1909; the contract complained of does not terminate until 1930. The extent of the contract's duration does not, however, of itself show any detriment to the Federal company, and the only testimony given on the subject, that of Sweeny, was to the effect that a contract of long duration was highly desirable to the said Company. A ground alleged as showing detriment to the Federal company is in the increase in the average price of lead for the years from and including 1903 to 1905 over that for the period of ten years preceding the year 1903. While it is true that the average price was higher, yet the difference is not so great as to justify the court in finding that any disadvantage suffered by continuing in said contract the figure of $4.10 was not offset by the other advantages gained by the Federal company, as testified to on the trial. In other words, the court would be placed in the position of determining that a fraud had been committed because, according to the court's judgment, on purely a question of business policy, the wisest course had not been adopted. This view, taken with what is hereinafter said concerning the attitude of those other than the plaintiffs, really interested, precludes the court from finding that the said difference in price is sufficient to establish flagrant fraud and thus avoid said contract. In order to justify the court intervening on behalf of the plaintiffs here, it must know that it is doing that which will inure to the protection and furtherance of the interests of the *cestui que* trust, as the minority stockholders of the Federal company must be regarded. They are entitled to demand the aid of the equitable jurisdiction of the court to set aside a voidable contract made by the majority stockholders if it appears that such contract is to their detriment. The plaintiffs own less than 2% of the stock of the Company. That fact, however, does not preclude them from being entitled to raise the question now being considered. It has an important bearing, nevertheless, upon the question, first, as to the desirability of the contract itself, and, secondly, as to whether the court may regard the plaintiffs as adequately representing the will of the minority shareholders. It relates to the desirability of the contract because, so far as the record in this case shows, the plaintiffs are the only minority shareholders who have objected to the agreement. It is therefore to be inferred that those occupying a like position have acquiesced, if not approved. For all that is before the court, they may regard the arrangement as a desirable one. The annual meetings that have taken place since 1905, when the contract was made, so far as appears, have not been characterized by any protest or objection. The plaintiffs themselves apparently found no fault with the contract between the making thereof in 1905 and shortly before the bringing of this action in 1913. It is true that the plaintiff Norman had only held his stock for a comparatively brief period prior to the bringing of the action, but that would entitle him to less consideration than his co-plaintiffs. Circulars were sent out to other stockholders by the plaintiffs calling their attention to the matters of which plaintiffs now complain, and yet there is no evidence that any of said shareholders wished to join in the plaintiffs' protest or were in sympathy with it. Neither must it be lost sight of that said contract was approved at the annual meeting in 1905, at which the shareholders were fully represented. In the face of the attitude taken by the stockholders, as thus briefly described, I think that the court would assume a grave and unwarranted responsibility in setting aside a contract after years of its operation at the demand of only 2% of those interested, on the ground that its continuance is a detriment to all. It does not seem in these circumstances that the court would be responding to a demand from those who were really the *cestui que* trust. In view of the conclusions I have reached, it becomes unnecessary to discuss the other separate defenses raised by the defendants, and the complaint is dismissed.

Dredging in Victoria, Australia

The Briseis Tin & General Mining Co., which produces tin in Tasmania, also has four dredges working in Victoria, and results in 1913 were as follows:

Operation.	No. 1.	No. 2.	No. 3.	No. 4.
Time worked, hours	5,378	2,408	5,381	5,898
Gravel treated, cubic yards	325,300	126,300	376,000	441,200
Gravel per hour, cubic yards	60	52	70	75
Average depth, feet	30	24	37	22.5
Gold recovered, ounces	1,392	542	2,146	1,684
Average per yard, cents	8	8	10.6	7
Cost per yard, cents	6.8	7.64	7.46	4.92
Working profit	$3,700	$390	$11,500	$9,600

No. 1 boat worked in fairly tight gravel overlain by 12 to 16 ft. of clay matter and old logs. The depth of gravel is now 38 ft. The top tumbler shaft broke in February, and 688 hours was lost. Tight ground made necessary renewals to buckets, ladder, and tumblers of No. 2 boat. Gold returns were erratic. The top tumbler spur wheel of No. 3 failed, but little delay was incurred. Tough ground made heavy wear on links and lips of buckets. No. 4 mainly turned over old workings, although in places a very tough clayey overburden was cut out. The resoiling conditions imposed by the Government are a source of considerable expense, and leveling of the soil deposited is likely to become more so.

CEMENT tested by the Bureau of Standards at Washington, D. C., amounts to 6,158,108 bbl., mainly for the Panama canal.

DISCUSSION

Readers of the MINING AND SCIENTIFIC PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Methods of Testing Placer Gravels

The Editor:

Sir—The paragraph, in my article on 'Methods of Testing Placer Gravels', published in your issue of July 4, relative to the number of pans of gravel contained in a cubic yard, could have been made considerably clearer had I used the words "panable material" instead of "gravel." That is, my figures as given refer entirely to the number of pans of panable material contained in a cubic yard in place. By "panable material" is meant the sand and small stones which may be conveniently thrown into the pan and washed.

It is readily seen that a cubic yard of sand, or very fine gravel, can all be taken into a pan and washed, filling in the neighborhood of 150 to 160 pans. Therefore a cubic yard of fine gravel contains the maximum number of pans of panable material. On the other hand, taking an exaggerated case, a gravel may be of such a degree of coarseness that a cubic yard in place might consist of but five or six large sized boulders, too large to be put into a pan for washing. In this instance the only part of the cubic yard which could be panned, or would be a producer of value, would be such fine material as filled the interstices between the boulders; this might amount to only 9 or 10 full pans. Hence this gravel would contain 10 pans of panable material to the cubic yard.

In sampling by panning, it is very necessary to take into consideration the amount of value-producing, or washable material contained in a cubic yard. For example, a gravel bank is to be sampled, a pan of the material is picked out and washed, from which is obtained, say, 10c. in gold. Were this bank composed entirely of sand or fine gravel all of which could be washed, it would be safe to assume that every pan would contain a like value of 10c. in gold, thus giving the gravel a value of 150 times 10c. or $15 per cubic yard. I have taken it for granted, in order to make the example clearer, that gold is distributed evenly throughout the cubic yard.

On the other hand, suppose the gravel were very coarse, composed chiefly of boulders, and that the sample has been obtained by picking out the fine material filling the spaces between them. In this case, a large proportion of the gravel in the cubic yard being composed entirely of boulders, would not yield any gold or admit of being washed in the pan; therefore consideration must be given the smaller portion from which the 10c. per pan will be obtained. Upon investigation it is found that there are but 30 pans of this panable material, hence the deposit has a value of 30 times 10c. or $3 per cubic yard.

An average gravel contains from 60 to 70 pans of panable material to the cubic yard.

WALTER J. RADFORD.

Breckenridge, Colorado, July 20.

The Editor:

Sir—In your issue of July 4, Mr. Radford, in his interesting article on sampling of placer deposits, refers to the accuracy of the averages of drilling methods, and speaks of such drilling continued so as to give as much as eight holes per acre. Such close drilling is not, I believe, usual, and in most cases not necessary; first, as being too expensive and consuming too much time, and secondly, as not altering sufficiently the first results of the more widely scattered holes. In support of this statement I beg to append three maps of actual drilling on ground of the Yosemite Dredging & Mining Co. here at Snelling.

The tract in question, comprising 30 acres, lay on the opposite side of the river from the general mass of the ground and was left until the last for this reason. It was of importance to us to know whether this area was profitable, as, if so, we would cross the river, and dismantle the boat close to the county road, thus saving much distance in hauling. We therefore drilled the holes as per the first map; 400 ft. apart up and down the stream, by 200 ft. across the flow, making 20 holes in all. The map shows the depth and the value as shown by the samples. The area was in part badly overgrown with brush, and in part in a slough, so we had to drill a few holes rather out of alignment. The top soil, consisting of sandy loam, was about an average of 6 ft. deep; below this was gravel consisting of small cobbles and sand. The bedrock was soft lava ash.

The average of these holes, figured in the regular way, is 5.29c. per yard. We use the '0.01 formula' in our estimates, and for the probable dredge yield, deduct from this 20% for losses. This would make the probable value of the area only 4.32c. Moreover, in this area there are three high holes—25c., 14c., and 20c. If we cut these in half, as being freaks, we get a value for the area of 3.63c. and 2.90c. dredge yield.

To see if there was not a possible area of sufficient value to warrant dredging, we then went over the area a second time, spacing the holes as in map No. 2, and for this prospecting we obtained an average of 4c. per

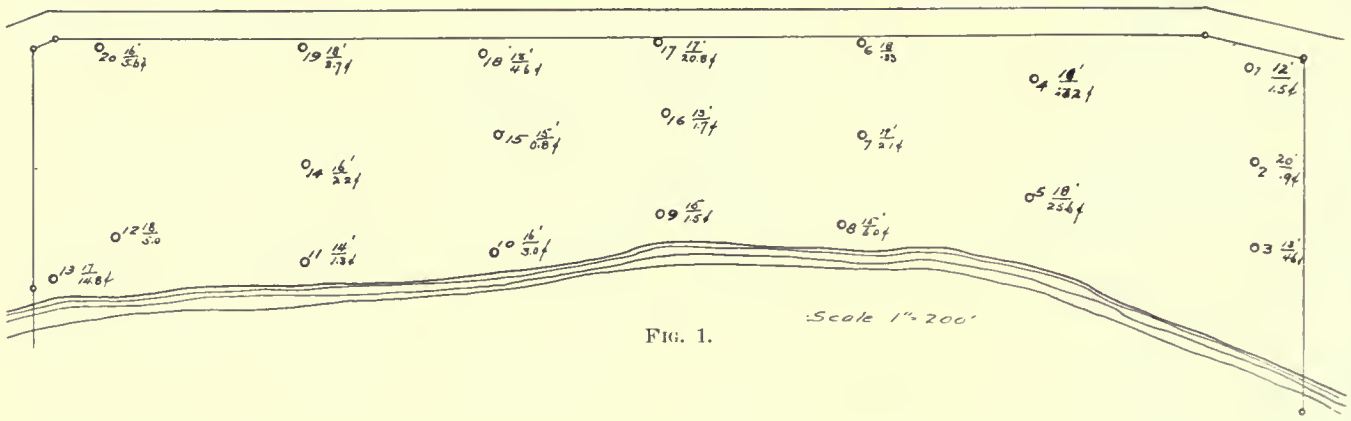

FIG. 1.

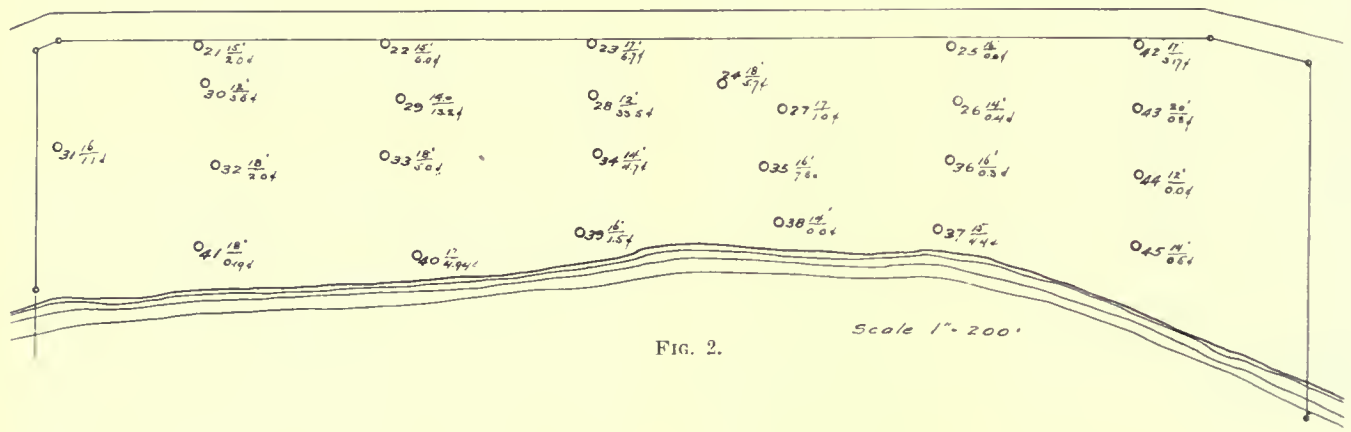

FIG. 2.

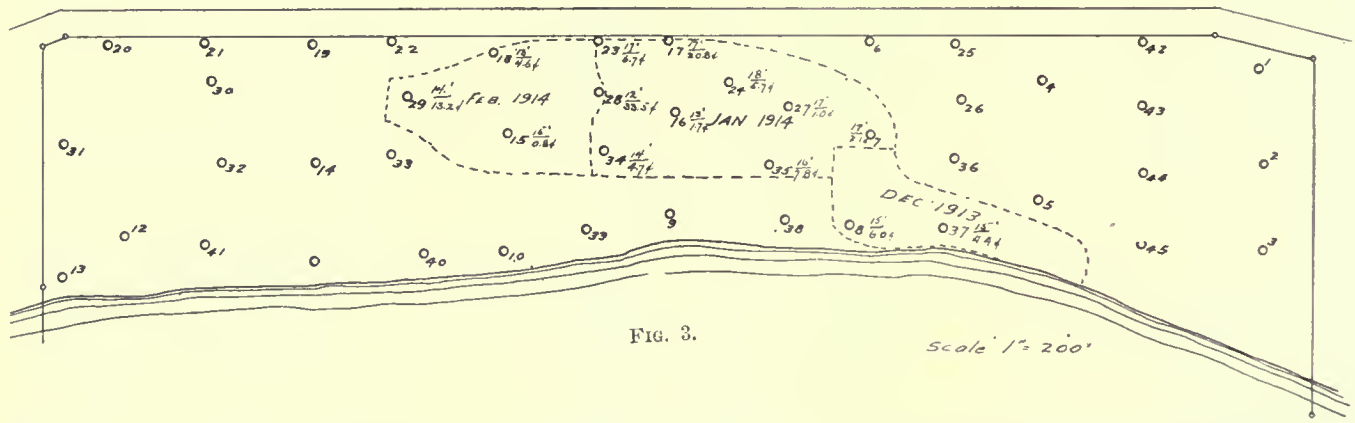

FIG. 3.

yard, drill yield, or 3.2c. dredge yield, including two freaks of 33c. and 13c. If we cut these in two, we have drill value of only 3.27c. and dredge value of 2.61 cents.

These two samplings, therefore, checked within a small fraction of a cent against each other, and the total average of both, which is for 45 holes in 30 acres, 4.57c., including all holes, or 3.42c. if half the freak holes be deducted. The comparison would therefore be: first 20 holes, 3.63c.; second 25, 3.27c.; of all 45, 3.42 cents.

After much discussion we selected a piece of the ground, crossed the river and dredged as shown in map No. 3, seven acres. This dredged area covered 14 drill-holes whose average value was 7.75c., or if we deduct as before the half of three high ones, 20c., 33c., and 13c., we get 5.55c. as the drill value, or an expected dredge yield of 4.44c. The records of our bullion product shows for these three months a yield of average 6.74c. per yard. In other words, we saved by the dredge a little more than 80% of the drill returns of all holes, including the freaks.

On another piece of ground in which we had 66 drill holes, covering the operation of over a year, we recovered the value indicated by all holes, freaks and all, less 80%, less 5%. This was in very loose river wash with no top soil at all. Many holes showed a value of only a cent or less; others ran up to 66c., and the average was approximately 9c. per yard.

Following this experience, we have recently purchased a piece of ground on this river on which we drilled one hole to about 1.5 acres, and we would have considered continuing this work until eight holes to the acre had been drilled, an extravagance not warranted by the difference in final results.

JAMES W. NEILL.

Snelling, California, July 15.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

QUICKSILVER LOSS at the Great Boulder mill, Kalgoorlie, in 1913 was 0.133 oz. per ton of ore treated.

CYANIDE CONSUMPTION at the Great Boulder mill, Kalgoorlie, in 1913 was 0.797 lb. per ton of ore treated.

NET ELECTRIC OUTPUT of the power-plants in the Canal Zone were as follows in May: Balboa, 7302; Empire, 100,840; Gatun, 624,360; and Miraflores, 1,785,260 kilowatt-hours; compressed air, 105 lb. pressure, amounting to 290,388,650 cu. ft. of free air was produced at Balboa, and 85,533,309 cu. ft. at Empire.

A WHITING electrically driven hoist at the Turf mines shaft of the Village Deep mine on the Rand is now successfully run with only one coil of rope around the reels, instead of three coils, as has been the practice where the Whiting is driven by steam. In this instance the efficiency has been increased considerably. The engineers on the mine, B. Gray and J. H. Rider, were responsible for this improvement.

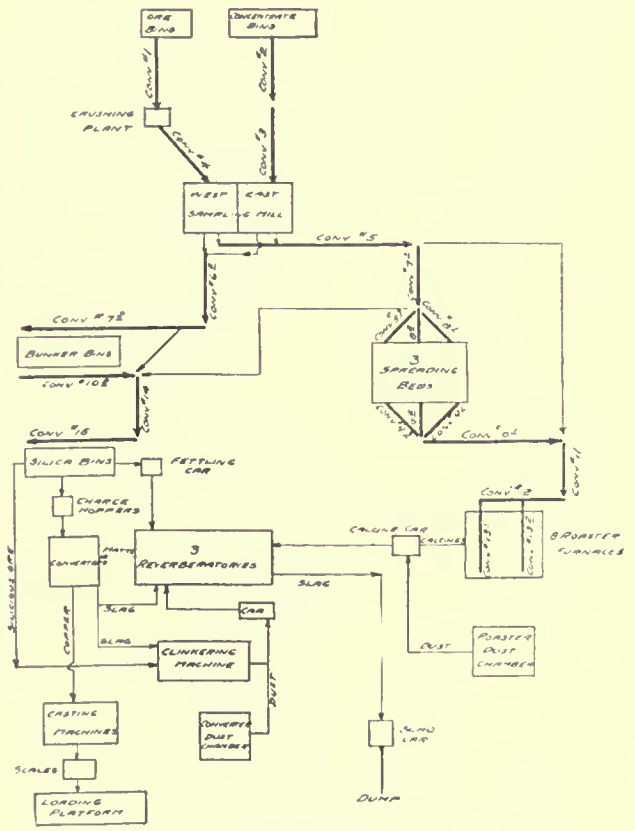
NODULIZING FLUE-DUST at the Chrome, New Jersey, refinery of the United States Metals Refining Co. is done by feeding it into a 6 by 60-ft. oil-fired kiln, standard cement practice size, lined with 6 in. of brick, on inclination of $\frac{7}{8}$ in. per foot to the discharge end, and working at $1\frac{1}{2}$ r.p.m. A granular sand can be made with about 8, a first-class smelting product with 12, and great chunks with 16 gal. of oil per ton. Firing has to be carefully done.

DIAPHRAGM is a word of Greek origin meaning to fence or enclose. A baffle, on the other hand, has been defined as something for deflecting, checking, or otherwise regulating flow. A diaphragm may thus refer to a partition, but never to a deflector, and its use in connection with the baffles sometimes found in cone classifiers is illogical. Diaphragms are used in pressure gauges and aneroid barometers. In this case they are flexible and connected with suitable recording apparatus.

APART from the Homestake, which operates two hydroelectric plants of its own and is building a steam-actuated auxiliary, all but three or four of the mines of the Black Hills district, South Dakota, are operated by electric power purchased from the Consolidated Power & Light Co. This concern operates a steam-driven generating plant at Pluma, and a water-power plant on Redwater river. It also buys all of the surplus power generated by the Dakota Power Co. at the latter's hydroelectric installation on Rapid creek near Pactola.

UNIT CONSTRUCTION COSTS of the new smelter of the Arizona Copper Co., Clifton, Arizona, are discussed in the July *Bulletin* of the A. I. M. E. by E. Horton Jones. A summary of the details is as follows:

Account.	Total.	Account.	Total.
Engineering	$100,650	Roaster dust chamber flue	12,859
Yard tracks, etc.	156,326	Boiler and blacksmith shop	21,449
Receiving bins	44,185	Machine and carpenter shop	27,356
Crushing plant	9,269	General office	1,395
Sampling plant	34,109	Warehouse	13,603
Bedding plant, etc.	150,939	Laboratory	6,144
Roasting plant	136,735	Sample room	2,826
Roaster dust chamber	49,664	Miscellaneous	37,186
Reverberatory plant	328,945	Indirect expense	140,278
Converter plant	216,033	Power plant	434,703
Converter dust chamber	27,814	Oil supply sump, etc.	40,619
Conveying system	45,411		
Chimney	45,471	Total cost	$2,105,020
Reverberatory flue	13,454		
Converter flue	7,602		



FLOW-SHEET OF ARIZONA COPPER CO.'S SMELTER. HEAVY LINES INDICATE CONVEYORS.

This is the latest smelter in Arizona, the Calumet & Arizona starting some time before. The monthly output of copper is about 3,500,000 pounds.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

RESUSCITATION OF OLD MINES IN THE RUSSIAN EMPIRE; RESULTS AND PROSPECTS OF THE KYSHTIM, AND OPENING THE GUMESHEVSKY AND SYSSELSKY MINES.

As remarked in a recent editorial paragraph of the *Press*, many of the less important copper mines receive proportionally a large amount of booming. The Russian copper mines certainly receive a lot of notice, but, though comparatively small producers, they are of sufficiently economic importance to attract the attention of the public and of technical men. For one thing, the Russian mines are only just emerging, by the aid of English and American engineers, from the pre-Agricola age of technology; and second, the muddled finance of the local owners has required a tremendous lot of straightening. Another fact that makes the Russian schemes attractive is the high import duty, which enables the home producer to obtain £25 per ton more than the standard price throughout the rest of the world. The Kyshtim presents an excellent example of the transformation of an old-fashioned property into one that can truthfully be called a model. Most of the engineers and scientists come from the United States, such as R. Gilman Brown, Walter G. Perkins, H. W. Turner, and A. W. Stickney; while the financial situation was saved by H. C. Hoover. As regards finance, £250,000 was subscribed in cash as part of the share issue, and subsequently £650,000 was raised by the issue of debentures. The holders of the debentures have already changed into shares, £1 nominal shares being taken for each £2 10s. in debentures. The share capital now stands at £1,253,800, and dividends at the rate of 22½ and 25% have been paid for 1912 and 1913. During the year 1913, 7971 tons of copper was produced, and 7832 tons was sold at an average price of £94, yielding a profit of £525,986. The iron works brought a profit of £42,449, the forest department £27,013, and the sale of pyrite, on sulphur content, £2663. After the payment of all expenses the profit was £311;578, and the Company distributed £314,058 as dividends.

The directors have just issued the report of R. Gilman Brown, the consulting engineer. The amount of ore mined was 351,043 long tons, of which 135,349 tons came from the Koniukhoff, 165,389 tons from the Smirnoff, and 47,371 tons from the Tissoff. The average content was 3% copper, 1.86 dwt. gold, and 1 oz. silver per ton. The total ore treated at the smelter at Karabash was 322,700 tons, together with 20,867 tons of low-grade matte produced by the reverberatory at the old smelter from 17,153 tons of roasted ore, 14,530 tons of fine raw ore, and 26,542 tons of flue-dust. The blister copper produced at Karabash was 8413 tons, averaging 98.85% copper, 3.56 oz. gold, and 33.6 oz. silver per ton. At the refinery, 7971 tons of copper was produced, and precious metals worth £19 per ton of copper. The ore blocked out on December 31 totaled 356,000 tons averaging just under 3% copper; of this, 51,600 tons averaging 2.85% was in the Koniukhoff, 232,300 tons averaging 2.8% in the Smirnoff, and 72,400 tons averaging 3.59% in the Tissoff. The assured reserves as indicated by bore-holes and development are as follows: Koniukhoff, 505,000 tons; Smirnoff, 384,000 tons; Tissoff, 415,000 tons; and Amerikansky, 611,000 tons. In addition, the ore assumed to exist within an average of 50 ft. below bore-holes is: Koniukhoff, 198,00 tons; Smirnoff, 133,000 tons; Tissoff, 141,000 tons; and Amerikansky, 74,000 tons. The total of assured and assumed ore is 2,461,000 tons, estimated to average 2.7 to 3% copper. The average metal content of the ore blocked out appears to be lower than that of the ore hitherto mined. The explanation is that large amounts of lower-grade ore can be extracted profitably during current mining operations that would be otherwise lost. A new orebody has been disclosed two miles south of Tissoff. This has been called the Ivanoff. The oxidized portion, on which development has been done, is high in gold and silver. The diamond-drill has intersected the lode at depth, where it is 9 ft. wide, and averages 2% copper. Since Mr. Brown's report was received, a bore-hole at Koniukhoff has cut the lode at a vertical depth of 1400 ft., where it is 6¼ ft. wide and averages 4.3% copper, 12.4 dwt. gold, and 8.3 oz. silver per ton. This figure for gold is by far the highest yet obtained. The capacity of the electrolytic refinery has been increased to 10,000 tons per year. A reverberatory furnace is being built at Karabash, to take the place of the plant at the old works.

Another group of copper mines in the Urals that is now in the process of transition from old to new methods belongs to the Sissert Estate. This Company owns copper, iron, gold, and platinum mines. Of the mines, the Gumeshevsky is the oldest, and the oxidized ores there have been worked by open-cut for generations. There are also large amounts of oxidized ore on the dumps that are treated by leaching. The other property, the Sysselsky, was opened as recently as 1906. During the past year 26,532 tons of ore was smelted, yielding 1082 tons of copper, and 80,879 tons of ore and dump material was leached, yielding 234 tons of copper. In addition, 3625 tons of cupriferous pyrite was sold for sulphuric acid manufacture containing 4½% copper. At the iron mines, 24,265 tons of ore was raised, averaging 52% metal; and at the smelter and iron works, 17,937 tons of pig, 16,161 tons of ingot steel, and 9972 tons of manufactured iron were produced. The Company also reports a production of 5262 oz. gold and 811 oz. platinum. The Company has just paid a dividend of £37,750, being 5% on the issued capital of £755,000. Additional working capital is being subscribed. An option 173,000 £1 shares at 35s. has been exercised by the promotors, the Russian Trust & Finance Co., and a further option on 166,500 shares at 30s. has been granted. Extensive drilling operations are now in hand. At the Gumeshevsky, drilling is being done to prove the orebody below the open-cut; as the results were promising, a shaft has been sunk, and an oxidized orebody is being developed. Additional ore has been proved in the Sysselsky. At the Krilatofsky gold mine, 158,000 tons of gold-bearing quartz has been blocked out averaging 14s. 4d. per ton; this is to be used as a flux in copper-smelting operations. The most interesting development, however, is at the Degtiarsky, where gossan outcrops are being tested by trenching and drilling. One orebody, as far as proved, is estimated to contain 250,000 tons of ore averaging 3.2% copper, 1 dwt. gold, and 0.53 oz. silver per ton. Other orebodies give promise of excellent development. The smelting plant is being extended and rebuilt on modern lines. In connection with all these modern Russian ventures, it is worth noting that prospecting by the diamond-drill plays an important part, and in fact the value of this method of prospecting is being demonstrated in a remarkable and satisfactory manner.

CORDOVA, ALASKA

SITUATION OF CORDOVA DISTRICT.—BONANZA, RARUS, AND MOTHER LODE COPPER MINES.—WORK AT COPPER MOUNTAIN, LAKINA RIVER, AND MCKINLEY LAKE PROPERTIES.—GOLD PLACER CLAIMS.—CHISANA, NELCHINA, AND KATALLA DISTRICTS.

The Cordova mining district embraces part of the Copper River valley, some of the mainland, and numerous islands in the southeastern Prince William sound. Tributary to the town, which was located on the southeast shore of Orca bay in 1906, as the coastal terminus of the Copper River & Northwestern railway, then planning to build into the interior, is the entire Chitina and Copper River valleys, together with minor streams on the southern side of the Alaska range. Since the construction of the railway, much more country has been made tributary to it. Copper river long was known to natives as a stream which cut a copper belt, and travelers and geologists reported on it before the town of Cordova or a railroad were thought of.

The Bonanza mine, itself the reason for the construction of the Copper River & Northwestern railroad, and situated on the east side of Kennecott glacier, at the head of Bonanza creek, is the biggest shipper of copper from the Cordova district. It is owned and operated by the Kennecott Mines Co. Shipments aggregate from 100 to 120 tons per day. From 175 to 200 men have been employed, with a monthly payroll aggregating $20,000. Ore now is being taken from the 400-ft. level, transported by aerial tram 3½ miles to the end of the railroad, there concentrated and sacked, and placed on board cars. The most important new developments planned by the Kennecott Mines Co. embrace placing the Jumbo claim, adjacent on the northeast to the Bonanza, on a shipping basis. A tramway will be built to connect the Jumbo workings with the mill, a distance of 4½ miles. Material for the tram, which is the product of the American Steel & Wire

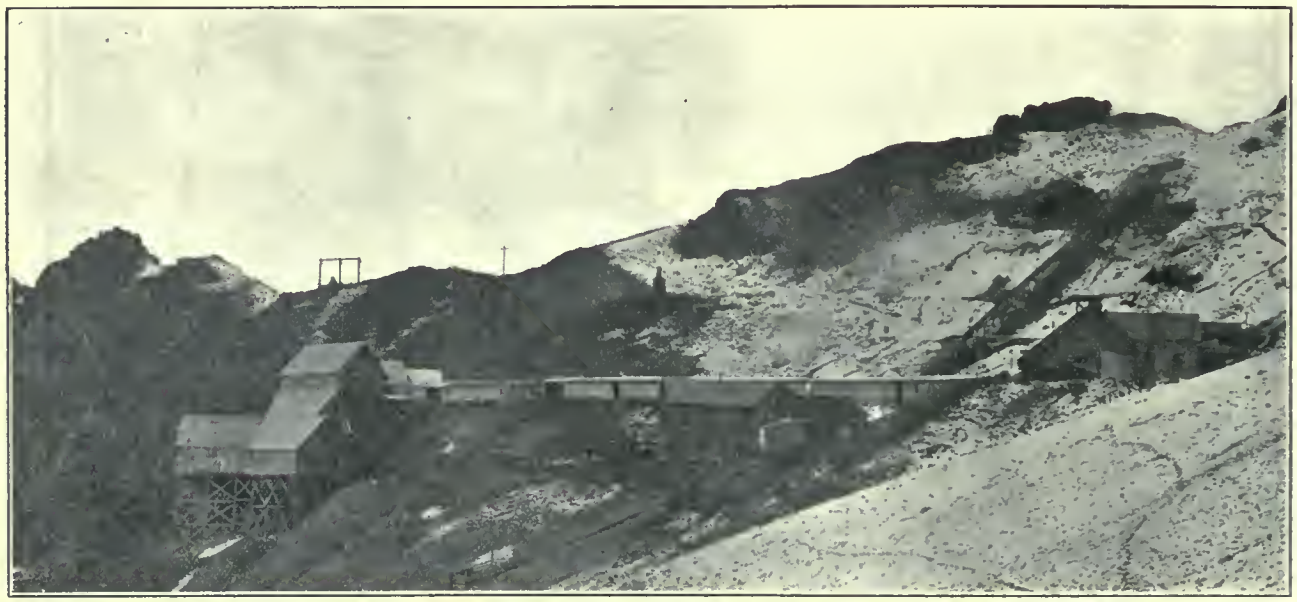
MAP OF PRINCE WILLIAM SOUND COUNTRY, SHOWING DISTRICTS DESCRIBED.

Co., is on the dock at Cordova, and will be shipped to the mine immediately. Work is now in progress. The Jumbo claim has paid all the development work done on it with the ore taken out, though hauled seven miles by teams during the winter. It is being developed from the 750-ft. level with stopes. Eight hundred feet of drifts has been run on the 500-ft. level. A shipment of 2500 tons of ore from the Jumbo was made in June. Fifty men are employed in development work. The Kennecott Mines Co. owns a group of 20 claims in the vicinity of the Bonanza property. W. A. Seagraves is superintendent in charge of the development of the claims.

The Mother Lode property, owned by the Mother Lode Copper Mining Co. of New York, situated across the mountain from the Bonanza, is being developed by two adits. Work soon is to be started on a sawmill, compressor building, and other structures at the mine, according to James J. Godfrey, president of the Company. A three-mile tram to the road will be built from the mine. A shipment of 525 tons of ore made last winter, after being hauled 16 miles over ice, yielded

by the Alaska United Copper Exploration Co., made up of California investors, are undergoing constant development. One property, near Kuskulana glacier, 15 miles from the railroad, has two adits with an aggregate length of 275 ft. Four men have worked there all summer. Another group of claims on Copper monntain is being developed by open-cuts. The third and most important group are the Westover claims, near Dan creek, in the Nizina section. A total of 550 ft. of adits has been driven on an irregular body of copper ore, which smelter tests show contains 25% copper. A tramway 1½ miles long to the mouth of Dan creek is being installed. From there the ore will be hauled 16 miles to McCarthy and shipped by railroad to Cordova.

The Alaska Consolidated Copper Co. owns two properties; one, the Rarus mine, 10 miles north of Mile 152; the other a group on Nugget creek. Alfred B. Iles is manager. A carload shipment of ore from the Rarus mine was made to the Tacoma smelter last winter. Development now under way consists largely of adits. These, too, are being driven



BONANZA MINE OF KENNECOTT MINES COMPANY.

561,484 lb. copper and 8915 oz. silver, according to the report of the Tacoma Smelting Co. Plans are being considered for an automobile-truck service to the railroad. It is stated that the Copper River & Northwestern railroad will build a spur to the mine if the mining company agrees to furnish a certain amount of tonnage. The spur, if built, would start from Mile 191.

E. F. Gray, president of the Great Northern Development Co., reached Cordova July 6, and planned to visit his properties and arrange for the season's work. One of his properties is at Copper Mountain, at Strelna, 12 miles from Mile 146. The property is a low-grade copper one, and but little work has been done since 1912, when a snowslide swept off the buildings and killed five workmen. Negotiations between Mr. Gray and the Copper River & Northwestern railway for the construction of the spur to the mine are under way. The Regal Mining Co.'s property, situated near the Bonanza claims at Kennecott, said to contain a deposit of high-grade copper ore, will be developed this summer by Mr. Gray, who is chief owner.——James S. Ramage and E. J. Bower recently completed the examination of copper properties on Lakina river, 12 miles from Mile 176, and are planning to erect machinery with a view to further development. Both men are directors of the Lakina Copper Co., holding Company for the Alaska Copper Co.——Three groups of claims owned

on the Hubbard-Elliott copper property on Elliott creek. A. E. Lathrop is chief owner in the claims, which are 15 miles from the railroad near Strelna.——Assessment work is being done on the Yanagita Mines Co.'s property near Mile 121. The property has been bonded. Two hundred feet of drifts has been driven on the orebody. The ore is copper bearing, with 9% nickel content. The Standard Mines Co. is opening up its property at Mile 109, and Frand Sellers is prospecting his claims in the same vicinity.——Mining men of the district look upon the McKinley Lake district, 15 miles from Cordova, as one of promise, although but little development work is being done at the present time. The Lucky Strike company is doing assessment work, as is the McKinley Lake Mining Company.

The placer output of the Nizina district, tributary to Cordova, is conservatively placed at $250,000 by George C. Hazelet. The Dan Creek Mining Co., of which Howard Birch is manager, operates on its claims on Dan creek, 25 miles beyond the end of the railroad. A hydraulic plant was completed in time to take advantage of the first water of the season, and has a daily capacity of 1000 yd. A flood in 1912 swept out the dams and ditches, and the entire year of 1913 was spent in changing the position of the dams. A sawmill, electric light plant, and necessary buildings make up the improvements. Three giants are in operation, one of them

used to stack tailing. The dirt is said to average $2.50 per yard. Forty men are being employed.——On Chittitu creek, George Max Esterly is operating a hydraulic plant, as is Ham Andrus on Rex guich, each with 40 men employed. Plans for a dredging company to operate on 30 claims owned by J. A. Hazelet on Chisina river are being considered. The claims have been prospected thoroughly with a Keystone drill.——Jack Miller continues to be the principal operator on Slate creek, a tributary of the Chistochina river, which in turn flows into the Copper. The creek was discovered in 1901 and has produced steadily for ten years. Miller took in 150 tons of pipe last spring and has completed the addition to his pipe-line. Among the claims being worked are the Tacoma, Four Black Dogs, and Humdinger. The 1914 output is estimated at $150,000 with the increased capacity that the Miller plant will have.

The Chisana district, which is reached by crossing Skolai pass from the end of the Copper River & Northwestern railroad, is not coming up to expectations. Latest information is that sluicing is in progress on ten different creeks, with

JACK MILLER'S OUTFIT ON SLATE CREEK.

500 men in the district. Fletcher Hamshaw, operating the original James holdings on an option, is reported to have been disappointed in his clean-ups. Dan McGuire, working on Dry guich, two miles below Bonanza, is reported to have found dirt panning from 12 to 15 cents. Wood in the Chisana district is scarce.——Another camp tributary to Chitina, on the Copper River & Northwestern railway, is the Nelchina, discovered during the winter of 1913-14. It can be reached by way of Knik and the Matanuska river, as well as by Chitina and Copper Center. Latest reports from the district are not encouraging. Pay has been discovered on two creeks. Miners are leaving for other fields.

At Katalla, the oil settlement of southwestern Alaska, one well is running, that of the Alaska Oil & Refining Co. Its output is five barrels per day of paraffine-base oil. The output of gasoline, distillate, and crude oil is sold to Prince William Sound ports.

Cordova looks forward to the opening of the Bering River coalfields, so that fuel will be available for smelting purposes. It is declared that the copper of Prince William sound could be smelted readily, as the interior ores, with their iron content, are the natural flux. Two complete surveys to the Bering River fields have been made by the Copper River railway from Mile 38, one by way of Katalla and the other by way of Lake Charlotte.

At present matters in the coal district are at a standstill pending passage by Congress of some legislation whereby the coalfields may be opened. Surveys now being made for a system of government railways to the interior would seem to insure that the present embargo on coal mining will be raised, but so far nothing definite has been accomplished in the direction of actual legislation.

LEAD, SOUTH DAKOTA

MOVING THE NEW HOMESTAKE HOIST PARTS, RECREATION HALL FINISHED, AND TAXES.—ORO HONDO WORK.—DAKOTA CONTINENTAL SUSPENSION.—NEW RELIANCE MILL WORKING.

To remove the machinery for the new hoisting plant at the B. and M. shaft of the Homestake company, from the railroad to the site of the plant, was a problem of some importance, when it is taken into consideration that the plant was to be erected at a point some 2000 ft. from the nearest railroad track, on a hill fully 200 ft. higher than the track. There was no suitable wagon-road over which to haul heavy loads, the two largest loads would be 25 tons each in single castings, and no good opportunity for building a road, as the ground is quite rough. The engineering department solved the problem by devising a scheme for an inclined railroad, on which a car could be operated by small hoisting engines, air driven, placed on the front end, with their cables attached to a stationary cable, securely anchored. The track is of 6-ft. gage, constructed of heavy wooden cross-ties and standard railway steel. Two bridges and considerable grading were necessary. In some places the grade is fully 20%. The car is constructed of steel, except the bed, in which 12 by 12-in. timber was used. It is designed to handle the maximum load, 25 tons. By its use, the heavy pieces being transferred to it from the railroad cars by means of a crane, the 1,000,000 lb. of iron and steel comprising the big hoisting engine is being delivered without trouble.

In its concrete construction the Homestake company is using Cheyenne river sand, hauled about 100 miles to Lead. Part of it is coming from Edgemont, on the C. B. & Q. railway, and recently 80 cars were contracted for at Oral, on the C. & N. W. railway, to be used in the new work at the B. and M. shaft, boiler plant, etc., which is contiguous to the tracks of the latter-named railway. Recreation Hall is practically completed, and with the installation of the library furniture, which is being received, and the removal of the library from its present location, the building will be dedicated with fitting ceremonies. Last year a complete readjustment of tax matters was ordered by the state tax commission, which ordered that all taxable property be carried on the lists at its full market value. The county assessors returned a low value on the Homestake property, which was promptly raised by the commissioners of Lawrence county. Later the figures were reviewed by the state tax commission, members of which questioned T. J. Grier closely as to his opinion of the value of the Homestake properties. They finally decided that a proper valuation of all of the Homestake property in Lawrence county, which includes the mine, milling plants, hydro-electric plants, water rights, timber lands, moneys, etc., would be $16,610,170. This year the valuation has been returned by the county assessors at $16,864,571, a little more than $250,000 above last year. As the average tax rate is 20 mills on the dollar on the bulk of the property, the combined state, county, school, and city taxes paid by the Company is over $300,000.

Good progress is being made in sinking the three-compartment shaft of the Oro Hondo property, which is being developed by J. T. Milliken of Colorado. The shaft was 1050 ft. deep, with 1500 ft. of cross-cuts on the 1000-ft. level when Mr. Milliken took hold. A steam plant had been erected, and was practically intact, with a hoisting engine and air-compressor sufficient for prospecting. The necessary repairs were made, two 100-hp. boilers added to the two already installed, two steam pumps purchased from the Homestake, the water column repaired and in places renewed, the lateral workings bulkheaded with concrete, and many minor details completed, all of which consumed three months' time. Jack-

hamer drills are being used in sinking, and with three shifts of miners employed. Mr. Milliken hopes to push things to a conclusion at an early date. He proposes to go to the 2500-ft. point, if necessary, to reach the southerly extension of the Homestake orebodies. The Oro Hondo shaft is 2600 ft. southeast of the Ellison shaft of the Homestake company.

Work was suspended by the Dakota Continental Copper Co. on July 15. No future plans have been announced. Starting early this year the workings were unwatered and sinking commenced from the bottom at 813 ft. At a depth of 850 ft. sinking was discontinued and a station cut at 825 ft., from which a cross-cut was advanced 240 ft. through exceedingly hard ground. One quartz vein was found, but it was barren of copper. Previous to sinking, a Rumsey triplex electric-driven pump was installed in the station on the 700-ft. level.

To facilitate mining 'an ore vertical' in the shales, which has an average width of close to 8 ft., Ingersoll-Rand stoping drills are being used at the New Reliance mine. This vertical lately has been developed until there is at present exposed fully 100 ft. of backs over a distance of 1000 ft. It will be put into the mill at a minimum cost, with the aid of the new drills. A small compressor, of Ingersoll-Rand make, driven by a 15-hp. motor, has been installed in a station in the adit near the first stope, which is being carried up in the vertical.

JOHANNESBURG, TRANSVAAL

MEETING OF THE CROWN MINES, LTD., RESULTS OF AMALGAMATION SCHEME, COSTS, DIVIDENDS, AND FUTURE LIFE.

During the second week of June was held the annual meeting of the Crown Mines, Ltd., the most important gold mining concern on the Rand. The chairman of directors set himself the task and quoted figures to prove that the amalgamation represented by the Crown Mines had been a success. There is no doubt that among the different amalgamations on the Rand, this one has been the most successful, but even this Company's dividend has fallen 10% since the merging took place, so that to the ordinary shareholder the advantages of the consolidation do not so readily appeal. Since this happened Rand companies have all had to suffer the disadvantage of higher legislative burdens, and increasing taxation, not to mention labor troubles. It is admitted that the Crown Mines working costs have increased since 1908 to the extent of 60c. per ton, despite the fact that ore reduction costs are 24c. per ton less, and the tonnage mined has increased 50%. Mention was made by the chairman that miner's phthisis insurance and compensation had cost the Company 10c., and attempts to allay the dust another 4c., and ventilation 2c. per ton. These increases, however, are more than met by 24c. decrease in treatment, and 9c. in pumping charges, so that the increase in cost of 60c. per ton still remains unaccounted for. It might in all fairness be expected that with such an increase in the tonnage mined as 50%, the working cost would decline considerably, but such has proved not to be the case, and to most people the position remains unexplainable. As regards the decline of dividends it may be said that while working costs have increased, the same proportionate increase is not apparent either in the yield or working profits. Then the effect of the issue of £1,000,000 of debentures must not be overlooked as consuming some of the profits, the whole of which has been expended in consolidating and concentrating mining operations without adding to the dividend. It is interesting to note that by the increased use of machine-drills for stoping purposes, and may be by the extended use of cheap white labor, the ore mined per native employed has increased from 12.3 tons per month in 1911 to 16.4 tons per month in 1913, working costs in that time being lowered from $4.64 to $3.94 per ton.

NEW YORK

EFFECT OF THE EUROPEAN TROUBLE ON NEW YORK. GOLD MOVEMENTS. COPPER EXPORTS, AND SILVER MINES.—FLOTATION LITIGATION.

Everything in the mining world has been overshadowed during the past week by the European war cloud, and everyone has been so interested in what might happen next, and what its possible and probable effects will be, that only perfunctory attention has been given to routine affairs. The European situation has already had profound effects in New York. The Stock Exchange closed on July 31, for the first time since 1873, after having withstood a flood of selling orders for as long as it seemed safe to do so. Nominally, the doors were only closed until the following Monday, but no one expects them to open for some time, unless there is an immediate marked improvement in the situation. The cotton exchange is also closed, and the German steamers which were to have sailed from New York on July 31 and August 1 remained at their berths, while a steamer which was already some distance at sea was called back by wireless. American gold has been shipped to Europe by the ton, the high exchange rate serving to send it out of this country with great rapidity. The Philadelphia mint sent 45 tons of gold coin to New York in one day, and the Secretary of the Treasury has announced that $500,000,000 of emergency currency will be provided for the use of banks in this country. Many people are wondering whether to deposit their cash in banks, fearing that they may have the same difficulty in getting it out again that was experienced in 1907. Americans in Europe are hustling to get home again and are having the utmost difficulty in doing so, since many of the steamship lines have indefinitely suspended sailings. Exports of copper to Europe have, of course, ceased, and for the time being the copper market is non-existent. For a while at least, producers will have to carry their stocks, and such companies as the Copper Range, Mohawk, and Wolverine, which sell most of their copper abroad, will be most affected. Silver-mining companies ought to boom, as the insistent demand for gold will draw that metal away from India and China, and silver will have to take its place. The situation is altogether decidedly confused, and no one understands very clearly just what may happen. It is certain that the United States will suffer little in comparison with Europe, but even 'comparatively little' may be quite enough.

The beginning of a suit against the Miami Copper Co. by the Minerals Separation, Ltd., and the announcement that users of the Callow process will also be sued, has put a keen edge on the general interest in flotation. The Minerals Separation people believe that they have valid basic patents covering the essential features of successful flotation work, and in order to get them sustained they will have to wage a campaign of suing in the several federal jurisdictions. It is too bad that Minerals Separation, in beginning its operations in this country, exhibited English secretiveness, rather than American frankness. If pains had been taken to secure the confidence and sympathetic coöperation of operators, the latter would have realized in the beginning that it was better business for them to secure the experience and engineering skill of the flotation company, rather than to try to work out methods for themselves, with the danger of an infringement suit always in the background. There seems to be an impression that the English company has been trying to hold up American operators for an undue proportion of the profits accruing from the use of flotation, but there does not seem to be any valid basis of fact for such a belief. It is a pity that there should be so much misunderstanding, for the net result of lawsuits seldom shows a gain to anybody except lawyers and court attendants.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Chisana

According to Lysle Brown, writing to Fairbanks, the new camp should be good for another year or so. 'Pay' has been found at 70 ft. on Dry Run, a tributary of Bonanza creek, two miles below Johnson City. Bacon is 75c., and nails are $1 per pound.——H. Harnshaw has a good number of men working on his options on 15 claims, which he will probably take up. He has paid about $70,000 to the owners, and has $50,000 more to pay.

ARIZONA

Gila County

(Special Correspondence.)—Less copper ore is being shipped from the Iron Cap mine to El Paso just now, and more development is under way. The orebody at 800 ft. has been opened for about 300 ft. east of the shaft, and a drift driven west at 160 ft. is showing rock containing iron and some copper. ——Seventy tons of 5 to 10% copper ore is being shipped daily to El Paso from the Superior & Boston. Development is resulting satisfactorily.——From the Warrior the daily tonnage sent to El Paso is about 100 tons.——In the Arizona Commercial a drift is being driven at 1200 ft. to connect with the Old Dominion at the same level.

Globe, July 23.

Mohave County

From the Tennessee mine in the Chloride district a large tonnage of ore is being sent to the Needles smelter. A good shoot has been opened at 900 ft.——Twenty miners have been added to the force at the Arabian mines.——The Frisco shaft is to be deepened and the mill started later. The latter may be remodeled and increased to 150-ton capacity.——A 5-stamp mill and concentrator are being erected at Little and Garnier's claim in the Wallapai mountains to treat gold-silver-lead ore.——The Union Basin company is shipping two cars per day of 46% zinc ore, containing a little gold and silver, to the Bartlesville, Oklahoma, smelter.——The Golden Gem gold mine has been unwatered to 350 ft., but timbers below 300 ft. are in bad order.——J. C. Hoffman is now manager for the Arizona Southwestern Copper Co. A shaft is to be sunk to 500 ft., and the mill remodeled.

Santa Cruz County

(Special Correspondence.)—The World's Fair mine is sending two cars of rich ore per week, and the Three R mine from 35 to 50 tons of copper ore per day. Both lots go to Douglas for treatment.

Patagonia, July 23.

Yavapai County

(Special Correspondence.)—California men have acquired 1600 acres of ground about Antelope Creek, near Stanton and Rich Hill, and nine miles west of Congress Junction. Coarse gold has been found nearby.

Congress Junction, July 23.

CALIFORNIA

According to the state mineralogist, F. McN. Hamilton, the more important field work on the mines and mineral resources of the state is all but completed, a year after the work was undertaken. Preliminary work on the report was started on August 1, and manuscript should be with the printer in the near future. A separate volume will cover the oil industry. In the general report all properties mentioned were personally visited by members of the staff of the State Mining Bureau. The work is the most complete ever attempted in the state.

Amador County

A large deposit of good talc has been cut in the pits of the Ione Clay Refinery.——The new 30-stamp mill at the Plymouth mine has been started, and 25 stamps are dropping.

Butte County

According to M. J. Cooney, president of the Forbestown Consolidated Mines, an important Canadian company has acquired its property at Forbestown.——Both Tokay and Muscat grapes have been sent East from J. H. Leggett's vineyard grown on old dredge tailing at Oroville. These grapes are of fine quality and much earlier than others in the state.

Calaveras County

The Calaveras Copper Co. is to be reorganized in Boston, and it is proposed to issue 60,000 preferred shares at $5 each par value, to bear non-cumulative dividends at 7% per year. The purchaser of this stock is to receive two shares of common stock of the present Company, which is 500,000 at $5, of which 373,750 have been issued. At the same time of this issue of preferred shares and payment of overdue interest, the mortgage of the Company is to be renewed for five years on the present terms. The $300,000 so raised is to be used as follows: immediate liabilities, accounts payable, $55,000; due for cash advanced to Company, $40,000; interest on unpaid coupons to July 1, 1914, $7700; interest on bonds due and unpaid to and including March 1, 1914, $81,000; making a total immediate liability of $183,700. Bond interest due on September 1, 1914, and March 1, 1915, amounts to $27,000. Probable bills receivable is placed at $28,000.

After paying everything there will be $117,000 available for general Company purposes. The property is to be placed in charge of a new manager, with for the present a consulting engineer approved by John Hays Hammond. Both favorable and unfavorable reports have been made about the mine, but the directors think that it has not been properly opened to prove what it is capable of producing. It was examined last February by S. M. Levy of Salt Lake City, who made the following statements: The property consists of 2835 acres of mineral, agricultural, and flowage land at Copperopolis. The mineral-bearing zone traverses the mineral land for about 13,200 ft., and in about 8000 ft. of this 15 shafts have been sunk from 50 to 1000 ft. deep. The last ore shipments made by the Company were from the latter depth, in the Union shaft. Fourteen shafts aggregate 4000 ft., and underground work totals nearly 26,400 ft. Water for irrigation and other purposes could be stored on the 1215 acres of flowage lands. On the property is a concentrating plant, which could treat 500 tons per day with certain improvements; sampling works; a blast and a reverberatory furnace to treat current concentrate and 100 tons per day of mine ore; a Nordberg compressor; hoist and head-frame at the Keystone shaft of 1000-ton capacity per day from 2000 ft.; dam for water supply costing $31,430; shops, offices, dwellings, etc. A total of about $1,950,000 has been spent to date on the property. Because of trouble with the smelter and lack of funds, work was suspended in June, 1913. Charles A. Stoneham, of the firm of Charles A. Stoneham & Co., has advanced the necessary com-

mon stock for the plan of reorganization from his own private resources. The directors are as follows: president, Charles M. Hayden; Oliver Ames, F. Lothrop Ames, James S. Ames, Samuel Carr, Gilmer Clap, and William J. Maloney; and secretary-treasurer, Herbert Goff.

The Royal Gold Mines Co. is being formed in Boston with a capital of $300,000 shares at $5 each par value. A large tonnage of $3 ore is opened in the mine. It was examined during the last few weeks by E. P. Jennings, of Salt Lake City, and Frank W. Page, of Boston. There is a 120-stamp mill on the property. Ore worth $2.50 per ton should yield a profit of $1 per ton.

Eldorado County

Owners of the Mt. Pleasant mine near Grizzly Flat hope soon to re-start work. As the ore is somewhat refractory, it is probable that a new mill and cyanide plant will be erected. ——A diamond-drill is working at the Pacific mine controlled by English interests.

Inyo County

Utah men who are leasing the Cerro Gordo mine near Keeler are said to be doing well. An ore-shoot has been opened for 150 ft. and 3 ft. wide, and has also been cut at 200, 400, 500, and 700 ft. depth. The present output is 20 tons of $50 silver ore per day. L. D. Gordon is in charge.

Nevada County

A temporary restraining order has been issued by the court prohibiting the Jerry Goodwin hydraulic mine at You Bet from being worked, on account of dirty water in the Bear river.

Placer County

A large dredge is to be constructed by L. Gardella, of Oroville, on property bonded by the Newcastle Mining Co. at Gold Hill, and bought by Mr. Gardella. The area is between Auburn and Lincoln.

Riverside County

In the Ironwood mining district, the Assets Realizing Mines Corporation of Los Angeles is developing about 300 acres at an altitude of 1800 ft. The claims include the Arica, Big Butte, Crescent, Eldorado, and January 1, 2, 3, 4, 5, 6, and others. Six veins run through the property having dolomite hanging and schistose foot-walls. About 18,100 tons of gold-silver ore worth $362,000 is ready for stoping, and dumps contain $60,000. There is a fair equipment at the mines. A 20-stamp mill lies at Blythe Junction, ready for hauling and installation. J. V. Priest is general manager for the Company.

Shasta County

On August 2 the Victor Power & Mining Co. paid at Red Bluff, Tehama county, $25,000 in cash to the Midas Mining Co. as a first payment of $175,000 for the Midas mine in Harrison gulch, Shasta county. W. H. Roberts, of San Francisco, is one of the largest shareholders in the Midas. R. D. Jackson is to manage the combined properties, and H. S. Waiste is to be superintendent of the Midas.

Additions to the Mammoth company's bag-house at the smelter at Kennett are practically finished. Three blast-furnaces are working.

Sierra County

The Great Henk, Bull Moose, Squires, and other mines, in Secret cañon, have been sold by George W. Henk to the Western States Mining & Development Co. for about $100,000.——Some lead-silver ore has been cut in the Tippecanoe mine above Pike City by J. A. McKenzie.

YUBA No. 14 DREDGE, NEAR MARYSVILLE.

Yuba County

With a capital of $250,000 and a mine in Esmeralda county, Nevada, the Congress Consolidated Mining Co. has been incorporated at Marysville. The president is I. Sanford; vice-president, M. V. Oschewski; secretary, George Richards; and treasurer, C. M. Honey——Dredge No. 4 of the Yuba Consolidated Goldfields Co. at Hammonton is being remodeled, a steel hull replacing the present wooden one. No. 3 boat is to be overhauled.

A first payment of $10,000 has been made by Guggenheim interests for 300 acres of dredging ground on the Yuba river near Hammond. The full price is $209,500. It is reported also in Marysville that the Natomas Consolidated is acquiring 600 acres adjoining. These properties extend from Yuba No. 14 boat to Park's Bar bridge, and then to the Narrows. Local people owned the land.

COLORADO

Colorado's mine output of the principal metals in 1913 showed a decrease in value of $1,871,668 compared with 1912, according to Charles W. Henderson, of the U. S. Geological Survey. The total gross value of recovered metals in 1913 was $35,449,298; $18,146,916 in gold, 9,325,255 oz. of silver, 87,620,364 lb. of lead, 7,298,269 lb. of copper, and 119,346,429 lb. of zinc (in terms of spelter and zinc in zinc oxide). There were decreases of $441,646 in gold and 12,876,383 lb. in zinc and increases of 1,113,185 oz. in silver, 12,378,097 lb. in lead, and 190,966 lb. in copper. The heaviest decrease in value was $2,439,974 for zinc, but there were increases of $582,031 for silver and $469,394 for lead.

The number of mines producing metals in 1913 was 858, of which 29 were placers, against 856 mines, of which 33 were placers, in 1912. In 1913 the ore mined or treated in the state of Colorado totaled 2,727,316 short tons (mostly measnred dry weight), an increase of 150,690 tons over the output of 1912. Of this total, 1,602,785 short tons went to gold and silver mills, 459,533 tons went to mills for concentration only, and 664,998 dry tons went crude to smelters; 217,865 dry tons of concentrate was treated at the smelters.

Boulder County

Rich sulpho-telluride ore has been opened by C. L. Neilson near Sunset. The discovery is similar to the Orphan Boy ore in 1894.

Gilpin County

According to the *Weekly Register-Call*, of Central City, reliable mining news from this county's mines is scarce, as the majority of operators refuse to give any details of work or production.

Lake County (Leadville)

A contract for power to pump water from the 'downtown' mines has been let by Jesse F. McDonald to the Colorado Power Co., the total being 1000 hp. The Down Town Mines Co. has purchased electric centrifugal pumps in Switzerland. ——A great deal of the zinc carbonate ore produced in the district comes from the Fryer Hill area.——The Siwatch Leasing Co. has secured a lease on the Siwatch tunnel and included properties in the Sugar Loaf district.——The new zinc smelter is now in full blast.——Another patch of two tons of gold ore in the Pat Connors lease of the Little Jonny assayed 303 oz. per ton.——Electric machinery is being installed in the Walker tunnel.

Ouray County

Profit of the Camp Bird mine for June is estimated at £9819.

San Miguel County

The Tomboy mill treated 11,500 tons of ore in June, yielding bullion worth $43,000, and 1150 tons of concentrate worth $47,000. Including the tramway profit of $1000, the total profit was $42,000.

Teller County (Cripple Creek)

An aerial tramway is to be erected to carry ore from the Midget mine to the Moon Anchor loading station on the high line electric road. There are 15 sets of lessees at the property.——With the 3c. dividend paid on July 25 by the Vindicator company was a circular from the president, Adolph J. Zang, covering the past quarter's work. No. 1 shaft was sunk to 1820 ft. and a station prepared at 1780 ft. This is equal to 1650 ft. in the Golden Cycle, and drainage is improved thereby. Shaft-sinking is again under way. Development at 1600 ft. was good, and No. 1 south vein is from 6 to 35 ft. wide for 600 ft. long, and of good grade. Work on No. 2, 3, and 4 veins opened several hundred feet of ore. No. 1 north vein, on this level, is 640 ft. long and 6 ft. wide of good grade. A spur or shoot from this is 20 by 80 feet. The steel frame of the concentrating plant is being erected, and machinery is ready for installation. A compressor which has worked for 15 years is to be replaced by an electrically driven machine costing $10,000. Extension of the Roosevelt drainage tunnel will greatly help the property, and $40,000 is to be contributed to the work by this Company. The output of the mine for the first half of 1914 was 12,000 tons, worth $250,000 net on Company account, and 8000 tons worth $160,000 on lessees' account. The latter produced $38,000 in royalties. The Company's total profit was $150,000.

Earnings of the Mary McKinney company for the first half of 1914 were $111,137, and expenditure $80,156. Three dividends, totaling $78,585, have been paid this year. The cash balance is $75,810.——A shipment from the Caley lease on the Jerry Johnson ground brought 96.55 oz. gold per ton.

Owing to continuous rain and subsequent seepage water, surface prospecting, ore haulage, and underground work in the district is being hampered. Both the deep levels of some mines and shallow shafts of others have been flooded. The main shaft of the Gold Dollar company has been temporarily shut down.——The output of the district is estimated by local authorities as follows, a railroad strike, floods, and bad roads reducing the yield:

Plants.	Tons.	Av. val.	Total val.
Golden Cycle	24,500	$20.00	$490,000
Portland (Colorado City)	7,500	20.00	150,000
Smelters	3,800	55.00	209,000
Portland (Cripple Creek)	18,000	2.44	43,920
Stratton's Independence	11,600	2.80	32,480
Colburn-Ajax	3,723	5.00	18,615
Kavanaugh-Jo Dandy	1,500	2.00	3,000
Gaylord-Dante	1,400	2.20	3,080
Wild Horse	1,100	3.60	3,960
Isabella	1,000	2.00	2,000
Total	74,123		$956,055

Dividends totaled $253,807.

Work has been actually started in extending the Roosevelt drainage tunnel, and good progress is expected.

IDAHO

The mine output of gold, silver, copper, lead, and zinc in Idaho, according to C. N. Gerry, of the U. S. Geological Survey, increased in value from $21,466,521 in 1912 to $24,149,049 in 1913. The production of all the metals except gold increased. The Coeur d'Alene region, the main producing area of the state, had a greatly increased production, especially in silver, lead, and zinc. The gold output had a value of $1,344,559, or $36,655 less than that of 1912. The production of silver increased from 8,294,745 oz., valued at $5,101,268, in 1912, to 9,989,193 oz., valued at $6,033,473, in 1913. There was an increase in the copper output from 7,492,152 lb., valued at $1,236,205, in 1912, to 9,592,966 lb., valued at $1,486,910, in 1913. All records were broken in the production of lead, which increased from 284,185,657 lb., valued at $12,788,355, in 1912, to 317,871,945 lb., valued at $13,986,366, in 1913. An unusual production of zinc ore increased the spelter output from 13,905,502 lb., valued at $959,479, in 1912, to 23,173,953 lb., valued at $1,297,741, in 1913. There were 384 producing mines in the state in 1913, against 408 in 1912. The total quantity of ore shipped and treated in 1913 was 2,451,592 tons, against 2,266,334 tons in 1912.

Shoshone County

The Bunker Hill & Sullivan company paid dividend No. 203 on August 4, amounting to $81,750. The total to date is $15,383,250.——Milling is to be resumed at the National Copper mine in a few weeks. Development was said to be a year behind shipping and mill requirements.— Affairs of the Idora Hill company are being settled, and work has been resumed at the mine.

MICHIGAN

Houghton County

The various mining companies have 17,205 names on their payrolls, and wages payable in July were $1,341,990, more than ever before. Details of men employed are as follows, according to *The Daily Mining Gazette* of Houghton:

Mine.	July 1914.	July 1913.
Calumet & Hecla	5,747	4,107
Ahmeek	818	830
Allouez	461	308
Osceola	1,230	1,143
Centennial	245	118
Tamarack	532	610
La Salle	106	43
Isle Royale	742	709
Superior	205	162
Winona	472	300
Wolverine	410	387
Mohawk	750	851
Quincy	1,561	1,483
Hancock	200	161
Copper Range	2,958	2,716
Franklin	68	322
Total	16,505	14,250

Others employed at small properties bring the present total to 17,205. Last year's figures are those of the day before the strike, July 22. The Calumet & Hecla and subsidiaries are employing over 10,000 men.

MISSOURI

Jasper County

The Granby Mining & Smelting Co. has put down 34 drill-holes during the past few months, cutting 6% blende at 200 to 250 ft. The ore is disseminated through flint, which underlies a hard cap of limestone. The Company has started shaft-sinking near the Mascot mine at Granby.——At the Golden Rule mine nearby, four drill-holes have cut 20% blende at 90 to 105 ft., and a shaft is to be sunk to open this ore.

Discussing the Joplin district recently, the *Joplin News Herald* gave the following opinion: As the year advances it becomes more and more certain that the immediate Joplin camp is losing in importance so far as productiveness is concerned. The passing years see strange changes in the relative positions of the various camps of the district. Some 10 or 12 years ago Galena, Kansas, was the heaviest producing camp of the entire district, which at that time took in the corners of only two states, Missouri and Kansas. Since then Oklahoma has been added to the list of producing states. After Galena had been crowded out of first position by the Joplin camp, the Missouri district was in the lead for several years. Later Webb City, Missouri, took the lead, the heavy production from the sheet-ground mines putting this camp in first place, with Joplin second, while Galena last year was crowded down to fifth place. It now seems that Joplin is no longer destined to occupy even second place, the new Miami, Oklahoma, district having gained so rapidly in the last few years that this field, which even now is second in production of lead ore, promises to be advanced in zinc-ore production very shortly. The Alba-Neck City, Missouri, district, which ranked well up toward the top of the list five or six years ago, dropped to as low as sixth place last year, but this year will probably show a much larger output, due to the opening of a number of heavy producing mines in that field. Lawton, Kansas, is a new camp that is showing remarkable gains. The Badger-Peacock district, in Kansas, which ranked near the top of the list several years ago, is today producing nothing, and all the rich old mines are filled to the surface with water.

MONTANA

Fergus County

Considerable ore has been opened in the Piegan-Gloster claims of the Barnes-King Development Co., and it is proposed to erect a stamp-mill and cyanide plant with a large capacity.

Silverbow County

The second quarter's report of the North Butte Mining Co. contains the following: Development totaled 3450 ft. The Granite Mountain shaft was sunk to 40 ft. below the 3000-ft. station. Stations were finished at 2200 and 2800 ft., and connection made between this and the Speculator shaft on the 2200-ft. level. Work on the Edith May and Snowball veins was satisfactory, while the Jessie vein was found faulted considerably. Production was 102,292 dry tons of ore and 6 tons of precipitate yielding 5,446,097 lb. copper, 331,359 oz. silver, and 336 oz. gold. On June 30, 1914, assets included cash, $282,978; supplies at mine, $51,766; and copper and silver on hand, $1,630,372; while liabilities included accounts payable, $145,947; advances on metals, $825,801; unpaid treatment charges (not due), $167,279; and surplus and reserves, $3,283,-142.

A quarterly report from the Davis-Daly Copper Co. shows that the Colorado shaft is down 2208 ft., in spite of high temperatures and a heavy flow of water. Work was done at 1450 ft., totaling 364 ft., and cross-cutting at 1750 ft. is under way. The level has caved a good deal. The shaft is to be sunk to 2600 feet.

Extraction at the new Elm Orlu plant at Butte is from 96 to 97% of the zinc content of the ore. The Minerals Separation process is used.

In order to curtail copper production, the Great Falls smelter and seven mines at Anaconda have been shut down.

NEVADA

Churchill County

The Nevada Hills mill treated 5540 tons of ore worth $7.27 per ton in June, with a net profit of $6904. Development totaled 547 ft., and 2059 cu. ft. at a cost of $1.04 per ton. The Company's resources are $228,847.

Esmeralda County

The estimated production of the Goldfield Consolidated mine in July is as follows: Ore mined, 24,575 tons; gross extraction, $314,000; operating expenses, $155,000; and net realization, $159,000.

Lander County

McCoy is a new mining district situated 30 miles south of Battle Mountain, on the Southern Pacific railroad, and promises to be a fair gold-lead-copper area. Rocks of the district are granite, basalt, limestone, sandstone, and quartzite. Gold ores are found in porphyry, while the other two ores are in limestone.

Lyon County

No. 2 furnace at the Mason Valley smelter has been repaired. During the last week of July the whole plant treated 4519 tons of ore.

Nye County

The West End Consolidated Mining Co. has declared a dividend of 5c. per share, or $89,424. The total to date is $357,696. ——A rich shoot of ore has been opened in the Extension at 950 ft.——The Tonopah Mining Co.'s second quarterly report shows that the yield was $612,290, at an expense of $315,759. Adding sundry income, and deducting exploration, and Brown patent suit ($4716), the net income was $351,404. A dividend of $250,000 was paid on July 21. The surplus is $1,638,-222.—Nine mines at Tonopah produced 11,998 tons of ore worth $228,650 during the past week.

The Round Mountain and Round Mountain Sphinx companies have been consolidated under the name of the Round Mountain Mining Co., thus ending years of litigation over extralateral rights in Los Gazabo claim. The Sphinx company was paid 175,000 shares and $20,000 cash for its property. The area now controlled by the new Company is nearly 800 acres. From about 110 ft. depth the Sphinx has produced $75,000. The Round Mountain is producing 5000 tons of ore per month, the June profit being $21,000. The Keane vein is 5 ft. wide at 700 and 800 feet.

NEW MEXICO

Santa Fe County

(Special Correspondence.)—The Santa Fe Dredging Co. is installing a new plant on its 600 acres near Golden, 15 miles south of Cerillos. It will be driven by electricity.——The old gold mine at Dolores is idle. It has produced over $1,000,000 from down to 500 ft.——A large company has been organized to construct a dam across the Rio Grande in White Rock cañon, 16 miles west of Cerillos, and about the same distance from Santa Fe. Electric power will be generated from a head of 500 ft. to supply nearby towns and mines.

Cerillos, July 31.

UTAH

Juab County

It is stated that mills using the Christensen process are to be erected at the Grand Central and Central Eureka mines.

Salt Lake County

Eight new prospecting drill-holes have been put down this year by the Utah Copper Co., proving ore to a depth of 450 ft. so far. The mines and mills of the Company will not be operated on Sundays until further notice. This will reduce the copper output by 1,500,000 lb. per month.

Summit County

At 700, 800, 900, and 1000 ft. the American Flag mine at Park City is opening well. About 100,000 tons of $15 ore is ready for the new mill, which is almost completed.——Ore has been opened in a raise from 1700 ft. in the Silver King Consolidated.

WASHINGTON

Ferry County

(Special Correspondence.)—In 1908 this county made an agreement and contract with Richard Mulray, of Republic, to lease the Republic and Cecelia quartz lode mining claims for two years, and give him the right to purchase them for $40,000 on or before March 3, 1910, the royalties agreed on to be applied to the purchase price. He and friends formed the Republic Leasing Co., which assigned its rights to the New Republic company. Some payments were made, and an extension of time given. On July 22, 1914, the county delivered a quit-claim deed to the Republic mine on the final payment of $16,949 by Frank A. Babcock, John T. Hollis, and Fred Kienbaum, parties of the second part of the deed and interested in the New Republic company. The rights of the latter passed to the Rathfon Reduction Works Co. In the quit-claim deed, Ferry county, as the party of the first part, for the sum of $40,000 paid by Richard Mulray and associates, as the Republic Leasing Co., the New Republic company, the Rathfon Reduction Works and the said parties of the second part, conveys to them the mining claims, subject to all rights of any person or corporation under the agreement, and without the party of the first part being responsible for any failure in title in the county to said property, etc.

In order to borrow money for its corporate purposes, the British Columbia Copper Co. has mortgaged its lands, mines, and other property in British Columbia and in Ferry and Stevens counties of Washington. On July 1, 1914, a mortgage or trust deed was recorded in Ferry county in which the Company, incorporated in West Virginia, conveyed to the Canadian Copper Corporation, Limited, of Virginia, the above properties so as to secure the issue of notes amounting to $1,000,000, finally maturing on April 1, 1923.

Republic, July 25.

CANADA

British Columbia

From March 1 to June 30 the Granby company's smelter at Hidden Creek produced 2,163,863 lb. of copper from 63,255 tons of ore.——A good deal of work is being done by the Quatsino company in the Elk Mountain district of Vancouver island, where it bought a copper property from Conrad Wolfe and other Spokane men for $500,000 last January. Ore production will start in a few months.——The quarterly statement of the chief inspector of mines, Thomas Graham, covering coal and metal mine fatalities in British Columbia, shows that there was one and nine men respectively killed, making eight and fourteen for the half-year.

Ontario

The Buffalo mill treated 6950 tons of 22.83-oz. silver ore in June, the recovery being 124,262 oz. No silver was sold during the month.——According to the president of the Nipissing Mines Co., E. P. Earle, the property is in good order despite rumors to the contrary. Net earnings for the first half of 1914 were $900,000, or 50% in excess of dividend requirements. The next period will equal this figure. Recovery at the low-grade mill is 90%, and at the high-grade mill certain alterations will eliminate the use of mercury. This Company is to develop the Teck-Hughes mine at Kirkland Lake on a working option basis. Ore worth $42 has been opened for 120 ft. at the 75-ft. level.——A recent shipment of 51 tons from the Tough-Oakes, in the same district, averaged about $500 gold per ton. At No. 7 level the shoot is 180 ft. long, averaging $100 per ton over 22 in. Excavating for the new mill is in progress.

Yukon

At the Treadgold property on Dominion creek operations are along usual lines, that of washing muck from the surface by sluicing. A new machine known as the Lubecker dredge and excavator is to be tried this season. This is a German invention and weighs about 70 tons. Digging is done by a series of buckets which drag gravel toward the machine. A depth of 70 ft. or a similar height can be dug. A washing plant will be placed near the excavator. Charles P. Dolan and David Elliot, of the Treadgold company, have been in England investigating the machine.

KOREA

The Oriental Consolidated reports as follows for May:

Stamps Working	240
Ore crushed, tons	28,065
Bullion from 9 plants (a record)	$169,038
Net profit	82,076

The Taracol cyanide plant treated a product worth $69,000, with 80% recovery. The Kuk San Dong mill was to be shut down for June, but will run in July or August.

MEXICO

Sonora

The mine-rescue helmet men who came to Cananea to put out fires in the Veta Grande and Oversight mines have returned to Bisbee, Arizona, with J. P. Hodgson, superintendent of the Copper Queen mines, and Wallace E. McKeehan, safety-first supervisor at the mines. Two stopes in each of the Cananea properties were burned out, between 400 and 500 ft. of timbered drifts, and No. 11 shaft of the Oversight. The latter fire was a difficult one to control.

PERSONAL

J. P. SMITH is in Alberta.

A. P. BUSEY was in San Francisco.

HENRY TSCHETSCHOTT is at Dawson.

H. S. GALE left Berkeley for Reno, Friday.

THOMAS T. READ has returned to New York.

W. H. LOVELETT is at Kanwa, Belgian Congo.

R. S. RAINSFORD has gone to Detroit, Michigan.

E. O. ULRICH is at Madison, Wisconsin, for the summer.

J. KOJIMA will attend the Salt Lake meeting of the Institute.

A. W. JENKS is up from the Argentine and will live at Berkeley.

ELMER E. FICKERT, of the University of North Dakota, is in San Francisco.

ALBION S. HOWE is at Minas Matabambre, Cabezas, Pinar del Rio, Cuba.

J. V. N. DORR is planning to attend the Salt Lake City meeting of the Institute.

H. C. HOOVER is taking an active part in the relief of Americans stranded in Europe.

NORMAN C. STINES has recently been in Sweden, but has returned to the Sissert mine in Russia.

THEO. C. NAEDELE has left the employ of the Braden Copper Co., and is now at Norwich, Connecticut.

THOMAS W. LAWSON has been for some time at the ranch of his son-in-law, in Creek county, Oregon.

ROSS HOFFMANN and KARL HOFFMANN are among Americans caught in Germany by the outbreak of the war.

JOSEPH RALPH is in Salt Lake City, where he will remain for an indefinite period, owing to business connected with liquidation of the Glasgow & Western Exploration Co., Ltd.

The SAN FRANCISCO SECTION of the American Institute of Mining Engineers held a dinner and meeting at the Engineers' Club, Thursday evening. Mr. C. E. van Barneveld discussed plans for the mining and metallurgical exhibit at the Exposition in 1915, and the general subject of Institute headquarters on the ground was also up. Arrangements were made for a party to attend the Salt Lake meeting of the Institute as representatives of the local section. Among those going will be C. W. MERRILL, F. G. COTTRELL, JAMES M. HYDE, J. C. RAY, H. FOSTER BAIN, WILLIAM HAGUE, and ROBERT H. BEDFORD.

The A. I. M. E. Salt Lake Meeting.

The program for this, August 10 to 14, includes the following: Headquarters will be at the Hotel Utah, and members and guests will register on the first day at Room C-38 and receive badges, booklets, and programs of the meeting. There will be an organ recital at the Mormon Tabernacle at 2:30 p.m., after which sight-seeing cars will convey the visitors around Salt Lake City. At 8:30 p.m. a technical session will be held in the ballroom of the hotel. On the second day the party will leave by special trains for the mines at Bingham, the Magna and Arthur concentrating plants, and the smelter at Garfield. The evening technical session will be held at 8:30 p.m., in the hotel. On the third day the party will leave by special train at 8:30 a.m. for a trip to the smelters at Murray, Midvale, and Tooele. The evening session for discussion of papers will be at the usual hour. On August 13 a technical session will start at 9:30 a.m. Members who do not care to attend this session will have the option of a trip to the mines at Park City, and some bathing in Great Salt Lake. On the last day, automobiles will convey everybody to Big Cottonwood cañon, while if desired members have the option of going to the Tintic district. A banquet will be held in the evening.

SOCIETY MEETINGS

AUGUST	
American Institute of Mining Engineers, Salt Lake City	10-14
British Association, Adelaide, South Australia	8
Canadian Mining Institute, Rocky Mountain branch, Banff.	
Lake Superior Mining Institute, Ishpeming, Michigan	31 to Sept. 3
SEPTEMBER	
American Chemical Society, Montreal	15-18
American Institute of Electrical Engineers	not fixed
Colorado Scientific Society, Denver	3
Illuminating Engineering Society, Cleveland	21-25
OCTOBER	
American Institute of Electrical Engineers	9
American Iron and Steel Institute	23-24
Colorado Scientific Society, Denver	3
NOVEMBER	
American Institute of Electrical Engineers	13
Colorado Scientific Society, Denver	7
DECEMBER	
American Institute of Electrical Engineers	11
American Museum of Safety	11-20
American Society of Mechanical Engineers	7-8

SCHOOLS AND SOCIETIES

The Institute of Metals will hold its autumn conference at Portsmouth, England, on September 10.

The University of California reports that it has 9000 correspondence students, of whom 1000 are taking extension courses in various subjects of university grade, and 8000 are taking free courses in agriculture.

At the American Institute of Mining Engineers' meeting at Salt Lake City next week, will be read 50 papers, which have already been published in the July and August *Transactions* of the Society. Among the papers are the following: 'Biographical Notice of Louis Janin,' by R. W. Raymond; 'Losses of Zinc in Mining, Milling, and Smelting,' by Dorsey A. Lyon and Samuel S. Arentz; 'Smelting Lead Ores in the Blast-Furnace,' by Irving A. Palmer; 'The Mill and Metallurgical Practice of the Nipissing Mining Co., Ltd., Cobalt, Ontario, Canada,' by G. H. Clevenger; 'Unit Construction Costs from the New Smelter of the Arizona Copper Co., Ltd.,' by E. Horton Jones (a most valuable article of 154 pages, a recapitulation of which appears on the 'Concentrates' page of this issue); 'Nodulizing Blast-Furnace Flue-Dust,' by Lawrance Addicks; 'Effects of the Bag-House on the Metallurgy of Lead,' by L. Douglas Anderson; 'Ancient Auriferous Gravel Channels of Sierra County, California,' by Mark N. Alling; 'The Descriptive Technology of Gold and Silver Metallurgy,' by A. W. Allen; 'Dip Chart,' by Howland Bancroft; 'Basic-Lined Converter Practice at the Old Dominion Plant,' by L. O. Howard; 'Tests of Rock-Drills at North Star Mine,' by Robert H. Bedford and William Hague; 'Mining Methods of the Copper Queen Mines,' by Joseph P. Hodgson; 'The Design, Construction, and Cost of Two Mine Bulkheads,' by Sidney L. Wise and Walter Strache; 'Leaching Experiments on the Ajo Ores,' by Stuart Croasdale; 'The Dorr Hydro-Metallurgical Apparatus,' by John Van N. Dorr; and 'Methods and Economies in Mining,' by Carl A. Allen.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

Metal markets are badly upset as a first result of the war in Europe. The Copper Producers' Association found it impossible to make a report for July, and cessation of European demand has already been reflected in the closing of the Great Falls plant and a number of Butte mines. As noted elsewhere, the Utah and other big companies are hereafter to observe Sunday as a holiday, and, in general, production is certain to decrease, at least temporarily. The tin market is even more sensitive. The Banca sale of July 30 was indefinitely postponed, and tin shipments by way of Europe are likely to cease altogether for the present. While they can easily be re-established by way of Panama, any such readjustment is not easy to make, and higher prices are probable for some time. Lead and zinc markets depend less on Europe, and are less likely to be affected, except as all business is likely to stagnate.

LOCAL METAL PRICES

San Francisco, August 6.

Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, August 6.—The copper market is at a complete standstill, and there are no quotations to be had. Dealers in London quote £70 per ton, or 15.30c. per lb. There is good demand for both lead and spelter. Between St. Louis and New York prices for lead there is a difference of 0.15c. No quotes are available for silver either here or in London. Samuel Montagu & Co., of the latter centre, on July 23 stated that the market was likely to remain sensitive to the daily attitude of Indian and Chinese operators. But with the present war nothing can be predicted regarding this metal. The American Smelting & Refining Co. has announced that it will buy silver ore at its smelters at 25c. per oz. cash for actual silver content, and the difference at a future date between that figure and whatever the market quotations may be. The Selby smelter will apply this new regulation. In the recent great sales of stocks in New York, copper and gold mining shares suffered less than other issues. Copper exports in July were 34,141 tons.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
July 30	52.25	June 24	56.21

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
July 9	37.50	July 23	37.50
" 16	37.50	" 30	37.50
		Aug. 6	No quotes

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	....
Mch.	40.20	39.00	Sept.	39.70	....
Apr.	41.00	38.90	Oct.	39.37	....
May	40.25	39.00	Nov.	39.40	....
June	41.00	38.60	Dec.	40.00	....

Owing to the war there is no quotation made in San Francisco for quicksilver. The principal dealers in the market here state that New York quotes $60 per flask. Supplies from Austria, Italy, and Spain, which countries produce about 94,000 flasks per year, against 20,213 flasks in the United States, are cut off for the present.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Date.		Average week ending	
July 30	4.75	June 24	4.85
" 31	4.75	July 1	4.75

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per pound higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

	1913.	1914.		1913.	1914.

MINERAL STATISTICS

The following data, covering the year 1913, is from the U. S. Geological Survey:

TRIPOLI AND DIATOMACEOUS EARTH

The production of tripoli and of diatomaceous earth in 1913 was the largest in the history of the industry, being valued at $285,821, more than twice as much as that of the year previous, when it amounted to $125,446. The amount of tripoli produced in 1913 was 20,797 short tons, valued at $216,581, and that of diatomaceous earth, 6586 short tons, valued at $69,240. Tripoli is used as an abrasive and for other purposes, but much of it is used in the manufacture of filters. It is also used as a paint, wood filler, metal polish, in soaps, in cleansers, and for making glass and facing foundry molds. Diatomaceous earth is used as an abrasive in the form of polishing powders and scouring soaps. Lately it has been found to be valuable in the manufacture of dynamite, as an insulating packing material for safes, steam pipes, and boilers, and as a fireproof building material.

COAL OUTPUT OF MARYLAND

Coal mined in Maryland in 1913 amounted to 4,779,839 short tons, valued at $5,927,046, according to figures compiled by E. W. Parker in coöperation with the State Geological Survey. This was less than the amount mined in 1912 by 184,199 short tons, but the value showed a gain of $87,967 and exceeded that of any other year since 1907.

The record of individual efficiency by the miners of Maryland is high. In 1913 the 5645 men employed in the coal mines of the state worked an average of 248 days, with a production per man of 847 tons. This is an exceptionally good average when it is considered that 4,373,920 tons, or 91.5% of the total, was mined by hand. The quantity of coal shot off the solid was only 293,950 tons.

POTTERY PRODUCTION

The value of pottery products of the United States in 1913, according to Jefferson Middleton, was $37,992,375, the largest yet reported, exceeding that of 1912 by $1,488,211. In 1913, as in 1912, only one variety decreased in value, namely, stoneware, which declined $236,211. The value of white ware, including china but excluding sanitary ware and porcelain electrical supplies, was $17,490,871 in 1913, compared with $17,006,736 in 1912, an increase of $484,135. If the value of sanitary ware and porcelain electrical supplies is added, the total for 1913 is $31,443,450. Chinaware showed an increase in value of $246,755. This product has increased in value almost steadily since 1902, the value in 1913, the highest recorded, being nearly twice as great as it was eleven years ago. Red earthenware showed an increase of $42,259 over 1912, white ware $237,380, and sanitary ware $312,583.

Ohio is the leading pottery-producing state in the Union, reporting for 1913 wares valued at $16,519,889, or more than 43% of the total, an increase of $1,011,154. Her principal pottery product is white ware, which constituted nearly 64% of the value of Ohio's entire pottery output in 1913. The second in importance is porcelain electrical supplies. New Jersey is the second largest pottery-producing state, producing wares valued at $8,838,545, or more than 23% of the total. West Virginia is the third in rank among the pottery-producing states, reporting for 1913 ware valued at $3,424,887. Pottery imported into the United States in 1913 was valued at $10,177,451, and this added to the domestic production made a total of $48,169,826. After deducting exports, domestic $559,163 and foreign $34,816, the net apparent consumption was valued at $47,575,847, of which the domestic production was nearly 80 per cent.

COMPANY REPORTS

ENGLISH CROWN SPELTER COMPANY, LTD.

This Company operates zinc mines in Bergamo province, Italy, and smelting works in Wales. In 1913 there was mined 4728 tons of carbonate and 2130 tons of blende, all high grade; also 13,229 tons of low-grade ore was concentrated. Calcined carbonate and raw blende shipped to Swansea averaged 41% zinc. The retorts treated this with other ores and yielded 7194 tons of spelter. The year's profit was £4044, and adding the last balance there was available £9375, of which £8400 was paid in dividends, equal to 10 per cent.

SNOWSTORM MINING COMPANY

This Company operates a property near Larson, in the Coeur d'Alene district of Idaho, and the report of the president and general manager, Leo Greenough, for the past year includes the following information: Shaft-sinking, cross-cutting, driving, and raising above and below the 1600-ft. level cost $50,150. There was mined 99,501 tons of ore, of which 20,108 tons assaying 4.16% copper and 5.41 oz. silver per ton was shipped, and 79,393 tons of 3.13% copper and 4.52 oz. silver was concentrated. Revenue from ore and concentrate was $505,224, and $53,775 from the boarding-house. Operating expenses were $257,069, including $50,784 for the boarding-house. Development, installation of flotation plant, acquisition of the Ada claims, and lease on the Missoula property cost $152,904. Net earnings were $156,045, and $22,492 was paid in dividends. Cash in bank on July 1, 1914, was $54,039, and total net surplus $226,647.

GREAT BOULDER PROPRIETARY GOLD MINES, LTD.

In the heart of the 'Golden Mile' at Kalgoorlie, Western Australia, this Company has 85 acres of ground, surrounded by the Perseverance, Lake View, Chaffers, Horse-Shoe, Ivanhoe, and Boulder No. 1 properties. The 1913 report of the general manager, Richard Hamilton, contains the following information on the various departments, in charge of the following, mine, J. Warwick; engineer, G. Ridgway; and metallurgist, A. Fraser. Development amounted to 2525 ft., a total of 113,013 ft. to date. Diamond-drilling, for which this mine is so noted, was actively continued without important results. A total of 2053 ft. was bored, making 50,125 ft. to date. Ore reserves are as follows:

Shaft.	Depth, feet.	Tons.	Av. content.
Main	200 to 2500	534,645	$14.61
Lane	200 to 500	22,644	19.30
Hamilton	800 to 1500	57,825	12.33
Total		615,114	$14.57

This is satisfactory considering that the lode is now in Horse-Shoe ground below 2650 ft. At 2800 ft. the Horse-Shoe was connected with the Main and Edwards shafts, improving ventilation. At a suitable time drilling is to be done between these shafts to test the area at a depth of 350 ft. below the 2800-ft. level. An interesting table is shown in the report giving the length, width, and value of the orebodies ready for extraction at the various levels. This shows that from 300 to 2500 ft. depth, inclusive, there is from 145 to 1398 ft. in length of ore remaining in backs, from 6.4 to 17.2 ft. wide, and averaging from $5.20 to $34 per ton in gold, at the Main and Edwards shafts.

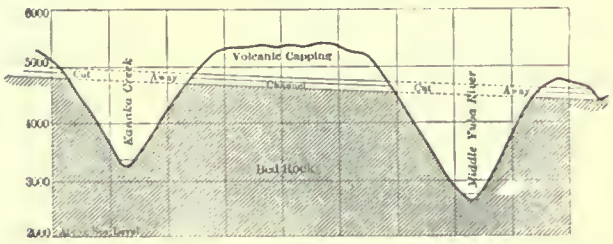
The dry-crushing, roasting, pan-grinding, agitating, and filter-pressing plant treated 189,469 tons of sulpho-telluride ore

yielding 54,319 oz. bullion by amalgamation and 99,052 oz. by cyanidation; also 37,934 tons of tailing for 3001 oz., making a total of 156,372 oz. worth £564,684. Residue averaged $1.59 per ton. Cost of development was 70c.; mining, $2.44; crushing and reduction $1.72; cyanidation, 70c.; and general and sundry, 30c.; a total of $5.86 per ton. The year's profit was £301,657, of which £262,500 was paid in dividends. After paying all other accounts, £1881 was carried forward to 1914. At the end of 1913 there were stores, livestock, shares in other companies, bullion on special deposit and in transit, and cash, worth over £220,000.

BRISEIS TIN & GENERAL MINING COMPANY, LTD.

Tin is recovered by this Company by sluicing in Tasmania, and gold by dredging in Victoria, Australia. The fourteenth annual report, covering the year 1913, contains the following information, from the reports of the consulting engineers, Messrs. Lake & Currie, and general manager, Lindesay C. Clark:

The tin property consists of tin drifts or gravels lying on what is called 'reef', and overlain by hard columnar and sometimes decomposed basalt. The drift is sluiced, and a good deal of the overburden undermined breaks down and is washed away, while the remainder is trammed to a dump. A total of 91,900 cu. yd. of overburden was moved in 1913 from the Ringarooma area, a total of 1,860,400 cu. yd. to date at a cost of 13.52c. per yard, and 560,000 cu. yd. of drift sluiced from the Briseis and Ringarooma areas. The drift



CROSS-SECTION O. BRISEIS MINE, LOOKING DOWN THE LEAD.

yielded 515 tons of black tin (SnO_2) averaging 74.6% metal. This was smelted at the Mt. Bischoff company's works at Launceston, and produced, after deducting the two units allowed for smelting losses, 374 tons of metal, realizing £69,428 net. This is equal to £186 per ton against £216 per ton in 1912. The cost was £35 per ton of black tin produced in 1913. The rainfall was low during the year, and hampered development and production, the total being 38.91 in., compared with 50.14 inches in 1912. The average quantity of water available was 116 sluiceheads, one Tasmanian sluicehead being 24 cu. ft. per minute. Estimates of reserves in the Ringarooma sections show 1,527,800 cu. yd. of overburden and 7,419,500 cu. yd. of drift, containing 4569 tons of black tin, at an average cost of £85 per ton of metal produced. Further details of mining operations will be given in another issue of this journal. The four dredges in Victoria handled 1,461,200 cu. yd. of gravel, yielding 8.24c. per yard at an average cost of 6.4c. per yard. Higher wages, increased price for firewood, and resoiling and leveling regulations imposed by the state government have resulted in higher costs.

Tin, gold, and sundry revenue made a total of £96,337 for the year. The profit was £37,728, and adding £21,447 from 1912, there was available £59,175. Of this, £30,000 was paid in dividends, £17,100 to 1914, and the balance for taxes, payments, and depreciation.

During the first quarter of 1914 there was treated 99,000 cu. yd. of overburden and drift, yielding 100 tons of black tin, containing 74.05 tons of metal. This was sold for £159 per ton.

BOOK REVIEWS

CRYSTALLOGRAPHY. An outline of the geometrical properties of crystals. By T. L. Walker. P. 204. Ill., index. McGraw-Hill Book Co., Inc., New York, 1914. For sale by the *Mining and Scientific Press*. Price $2.

While crystallization from solutions, sublimation, and fusion is important to various industries, the subject is fairly complex when the different systems of crystallization are considered. The shape of crystals is characteristic and more or less distinctive for each chemical substance. The author, professor of mineralogy and petrography at the University of Toronto, has used the Goldschmidt methods in his classes with good results, and prepared this work to have in the English language a connected elementary statement of crystallography from this point of view. Crystallographic investigations written by Victor Goldschmidt and William Nicol, John E. Wolff and Charles Palache, Victor Goldschmidt and A. L. Parsons, and Arthur S. Eakle are reprinted from various journals in this book.

USEFUL MINERALS AND RARE ORES. By Alexander McLeod. P. 114. Index. John Wiley & Sons, Inc., New York, 1914. For sale by the *Mining and Scientific Press*. Price, $1.25.

Several books have been published giving practical instructions in the search for and determination of useful minerals, yet this one is the result of 35 years' experience in active field work, and seems to be quite dependable for the prospector, miner, and others interested in mines. A cheap outfit and no skill is required in making the tests given. Instructions are given on panning, hardness, weight, and streak of minerals, prospecting hints, sampling veins, and testing for metals in the field. Forty-four pages are devoted to tabulated matter describing many minerals, their composition, color, weight, hardness, and the reaction on heating and acid treatment. Rare ores are more and more sought, and such ores as tellurium, monazite, uranium, vanadium, and others are explained, and means of identification given. Bound in leather and only 4½ by 6 in. in size, it is a handy book to carry about.

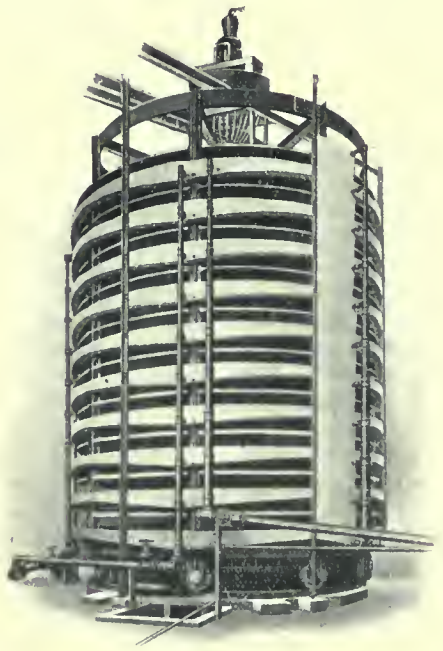
SUB-AQUEOUS FOUNDATIONS. A practical treatise including notes on the coffer-dam process for piers, and dredges and dredging. By Charles Evan Fowler. P. 814. Ill., plans, index. John Wiley & Sons, Inc., New York, 1914. For sale by the *Mining and Scientific Press*. Price $7.50.

In these days when foundations for buildings, power dams, machinery, and wharves are of such importance, and there are so many types of foundations used, such a compilation and discussion is especially valuable. Therefore, we find this work in its third edition, considerably revised and enlarged. The continued increase in weight of structures and loads to be carried necessitates great care in their foundations, yet collapses of buildings, bridges, and dams occur far too frequently, showing either a want of knowledge in construction or faulty work somewhere. The chapters cover such information as historical development, construction and practice, crib coffer-dams, pile-driving and sheet-piles, metal construction, cylinders and caissons, divers and diving, removing old piers, pumping and dredging, clam-shell dredges, drill scows and rock-breakers, dredges of all types, foundations, pier construction, cement and concrete, timber preservation, forms for concrete, and estimating costs. Sixty-nine tables give details of apparatus and material used in erecting structures, and 477 illustrations show more than many pages of description. Altogether, this work should be found valuable to architects, engineers, and contractors.

New Machines and Devices

Anaconda Slime Concentrator

The Anaconda slime concentrator, shown in the accompanying halftone, is a multiple-deck circular concentrator, the decks being conical in shape with a slope suited to the pulp to be treated. The decks are constructed of steel and concrete with a ladderway through the centre permitting easy access to all the decks and feed launders. This table is the result of five years' experimental work in the treatment of slime and is the nucleus of the 2500-ton slime plant being erected at Anaconda. The decks are placed one foot apart, vertically, and are carried on 8 steel columns at the periphery,



ANACONDA SLIME CONCENTRATOR

supported on a steel ring, which in turn is supported on wheels which run over a circular track. Thus the entire framework is free to revolve at a suitable speed, which is generally at the rate of one revolution every 3 to 10 minutes. The degree of roughness of the concrete surface depends upon the work to be done. The decks may also be made in concoidal shape or fitted with any form of riffling arrangement. The concentrator may be constructed with any number of decks from 5 to 20, as installed at Anaconda. For automatically feeding the proper amount of pulp to each deck, there is furnished a distributor which gives to each deck a proportionate amount of the total feed to the concentrator. The entire table is composed of steel and concrete which gives the machine a long life. The machine requires a comparatively low density of feed pulp, from 8 to 12% solids, and it is claimed will treat from 5 to 10 tons (dry) of slime per deck per 24 hours, or from 100 to 200 tons for the 20-deck machine, depending upon the character of the material treated. The concentrator requires a floor space, including walkways, of about 500 sq. ft. This machine is manufactured by the Traylor Engineering & Manufacturing Co., of Allentown, Pennsylvania.

Spanish Catalogs

In a campaign for business in the Latin-American countries there is one feature of publicity which has been generally overlooked by the manufacturers of machinery, and that is the class of literature for distribution among the native buyers in those countries. American manufacturers have spent thousands of dollars in the preparation of detailed catalogs in English for distribution in Spanish-American countries, which have been regularly consigned to the waste-paper basket, and expect to obtain a wide publicity and a market for their products by this means. While the majority of the large operators in these countries are English-speaking people, there is also a large percentage of smaller operators who are in the market for American machinery and on the mailing list of American manufacturers, to whom English catalogs and bulletins are as Sanskrit would be to the American operator. A catalog entitled 'Milling Machinery' is intelligible to English-speaking operators, but one entitled '*Maquinaria para Beneficiar Metales*' is intelligible to both English and Spanish-speaking operators in Latin-America. In anticipation of an expansion in Latin-American trade, the Allis-Chalmers Manufacturing Co., Milwaukee, Wisconsin, has prepared two attractive Spanish catalogs devoted to smelter equipment and milling machinery. The catalogs are illustrated and contain a large amount of descriptive material regarding the various products.

Commercial Paragraphs

THE U. S. ELECTRICAL MFG. CO., Los Angeles, Cal., has for distribution literature regarding the Type 'FR' motor manufactured by this Company. The motors are manufactured in sizes ranging from ¼ to 30 hp. and are guaranteed by the Company for two years.

POMONA MANUFACTURING CO., Pomona, California, has for distribution catalogue No. 1914 which describes in detail the construction and use of the deep well pumps manufactured by this Company. The pumps are especially adapted to lifts up to 300 ft. and have a wide variety of uses.

The DODGE MANUFACTURING CO., Mishawaka, Indiana, recently supplied the Presidio Mining Co., Shafter, Texas; Ahmeek Mining Co., Houghton, Michigan; Old Dominion Mining Co., Globe, Arizona; Calumet & Arizona Mining Co., Bisbee, Arizona; and the Alaska Gastineau Mining Co., Juneau, Alaska, with power transmission equipment.

BUSCH-SULZER BROS.-DIESEL ENGINE CO., St. Louis, Missouri, has for distribution an attractive illustrated bulletin which contains a discussion by Gordon Kribs entitled 'Cost of Generating Power with Diesel Oil Engines.' The article presents the actual operating results obtained under every-day operating conditions at the plants of the Texas Light & Power Co. The data presented are both interesting and instructive.

THE DENVER QUARTZ MILL & CRUSHER CO., Denver, Colorado, has recently received a contract to equip a complete 50-ton mill for the Crystal River Mining, Milling & Power Co. The equipment includes a 50-ton Denver quartz mill, Isabell concentrator, crusher, rolls, and accessories, all machinery to be shipped by August 10 to the property near Aspen, Colorado. The Company is also supplying a 25-ton Denver quartz mill, Denver crusher, and ore feeder for the property of W. H. Temme near Prescott, Arizona.

DOGMOBILES have come to be recognized as standard equipment for travel in Alaska between Nome and Lane's landing over the abandoned narrow-gage railway. With pulling on the up grades and coasting on the downs, the dog's lot in Alaska has been bettered somewhat at the expense of illogical railway investment.

PEACE IN MEXICO, which now seems at least a possibility before many months, will be more than welcome to those Mexican operators who have been taking a holiday on this side of the Rio Grande for the past year. While Carranza and Carbajal are reported as embracing in true Mexican fashion on one day and to be at sword's points on the next, the Constitutionalists and Federalists are at least nearer an agreement today than they were a month ago and the miners are optimistic.

SAD commentary upon the uncertainties of modern life is the fact that as we read war news from Germany, a belated mail brings the prospectus of an exposition planned to be held at Düsseldorf, May to November, 1915, commemorating one hundred years of art and culture. The program of the exposition is most attractive and we wish we might hope that the war would be sufficiently short to permit the plan being carried through. Miners are more concerned with the peaceful arts and industries than the glories of war.

ANNOUNCEMENT is made that a Johnson electric zinc smelting furnace will soon be in operation at Keokuk, Iowa, utilizing the cheap power supply of the Mississippi River Power Co. The furnace which has been in operation at Hartford, Connecticut, for several months will be moved to Keokuk and enlarged to 150 kilowatts capacity, or 5000 pounds per day. Meanwhile contracts have been let for the construction of a new 10-ton furnace at Keokuk. Negotiations with the provincial officials of British Columbia for the construction of an experimental furnace in the West Kootenay district have been dropped, for the time being at least, and the experimental tests on British Columbia ores which have been made at Hartford will be continued at Keokuk. The 30-ton shipment of zinc ore from the Burma Mines, Ltd., has been smelted at Hartford, and while the expected difficulties of treatment did not fail to materialize, it is stated that the results indicate that the ore can probably be successfully handled.

THE RADIUM bill providing for the conservation of radium resources by the Government will be considered next week. While its friends are optimistic as to its passing the House, it has met with a deadlock in the Senate and the possibility of it being given a hearing in the Upper House during the present session seems hopeless.

CALIFORNIA Industrial Accident Commission is receiving excellent coöperation from the employers in furthering the 'Safety First' movement. Preparations are being made by the Commission to hold public hearings for the purpose of discussing this timely subject and standardizing safety rules and regulations. It is gratifying to record that the work of the Commission is beginning to show results in the safeguarding of hazardous occupations and in many instances a reduction in insurance rates.

MEETING of the American Institute of Mining Engineers at Salt Lake City during the past week has been most successful, and the three hundred members who were in attendance left with the feeling of having spent a most profitable and enjoyable week as the guests of the Mormon city. From the opening address by Mr. D. C. Jackling to the closing banquet the meeting was divided between interesting technical discussion and visits to the neighboring mines and metallurgical plants. The high standard of technical papers presented at the Butte meeting last year was maintained in the present meeting and the diversity of discussion presented in the papers on mining and metallurgical subjects afforded a most interesting and excellently arranged program. In a succeeding issue we will present a detailed report of this meeting.

THE report of the Bureau of Domestic and Foreign Commerce for the fiscal year ended June 30, 1914, presents many interesting statistics relative to the nation's foreign trade for this period. The exports totaled $2,364,626,555, a decrease of over $100,000,000 from the previous year and the imports amounted to $1,894,169,180, which is the largest recorded and an increase of $81,160,946 over the imports of the previous year. The gold exports of the year totaled $112,038,529, while the imports were valued at $66,538,659, as compared with $77,762,622 exports and $69,194,025 imports for the preceding year. The foreign trade in silver showed a

general decline, the exports being $54,965,023 and imports $30,326,604 for the present fiscal year as compared with $71,614,311 exports and $41,268,516 imports for the previous year. It is indeed significant in light of recent European events to note that during the month of June the exports of gold to Europe totaled $48,107,064, as compared with $569,315 for the same period of the previous year and an average of about $4,000,000 for June for the past five years. The June imports for the past five years has been practically stationary at from four to five million dollars. It would seem that Europe's need for gold was anticipated. The return of the *Kronprinzessin Cecile* recently with $10,000,000 gold aboard for England and France, the second largest shipment ever made, lends a dramatic touch to the subject of gold exports.

STATUS OF THE METAL MARKET

Unsettled market conditions and the lack of quotations have resulted in smelters making provisional settlements on shipments of ore. According to the agreement reached by the smelters of Utah, gold will be paid for as heretofore and silver at the rate of 25 cents per ounce until further notice. The smelters will give to the shippers of silver ore their pro rata proportion of the first sales of silver made at the prices then obtaining in final settlement for the shipment, or on some other fair and equitable basis, which may be agreed upon between the shippers and the smelters. Advances on the copper content of ore will be made at the rate of 10 cents per pound and final settlement will be made with producers when market conditions again become settled. For the present no change will be made in the method of arriving at the price of domestic lead. In that from 25 to 35 per cent of the lead production of the United States has been exported during the past six months, there is reason to believe that a curtailment in production will be in order. In the general readjustment of production, markets, and prices, it seems reasonable that the certailment in production of copper, lead, and zinc to meet the market's demand will cause little fluctuation in the price of these metals, and the markets will be influenced to some extent by the transportation facilities which are available.

At the present time the copper producers are curtailing production to the extent of about 30,000,000 pounds per month, and there is reason to believe that this figure will be exceeded before long, as copper being a contraband of war is liable to seizure if consigned to the ports of belligerent countries and producers can look to no market for the present in this direction. The magnitude of the European market is evidenced by the fact that the present copper exports are valued at over one hundred and twenty-five millions dollars annually, a large part of which being exported to the present warring nations. The shipments of copper from America to Europe for the first six months of the present year averaged 81,700,000 per month, as compared with an average of 72,400,000 pounds per month for the whole of last year.

Lead and zinc are of an extremely secondary importance, and the total exports of about $2,500,000 will have a comparatively small effect upon American production and markets. The advances made in the prices of quicksilver and tin are interesting at this time and are steadily increasing under the influence of European troubles. The Banca sale in Holland which was to take place on July 30 has been indefinitely postponed and an unwillingness has developed on the part of the tin consumers to buy on the sterling basis because of the advancing rate of foreign exchange. Fear is expressed in some quarters that tin shipments may cease as a result of the present crisis.

The withdrawal of foreign vessels from the merchant marine to meet the calls of the belligerent governments of Europe has curtailed the export trade in steel, as this country is practically dependent upon foreign bottoms for this trade. The export business of the United States Steel Corporation amounts to about fifteen per cent of its total sales and this Corporation handles about seventy-five per cent of the export business in steel products. Although the United States government has taken steps to permit the transfer of foreign built ships to American register, there is much misgiving in shipping circles that this may become effective. The Steel company's vessels, which are under the British flag, will of course be transferred at once to American register. The Pacific coast demand for rolled steel products, which for many months has been supplied with foreign made steel, is now being met in the Eastern markets. This increase in demand from the West will have an ameliorating effect upon present conditions. The tin-plate situation is most precarious in that the American manufacturer is so dependent upon England and foreign boats for his tin supply. The Steel Corporation uses from 1000 to 1200 tons of pig tin per month, sixty per cent of which comes from the Straits Settlements by way of London, there being but few direct shipments to America. War risks will greatly curtail shipments from the Straits, with the result that the tin plate manufacturers are in a quandary as to how the demand is to be met. There is but one or two months' supply on hand at the present time, and with tin quoted at 62 cents per pound, the tin-plate manufacturer will be forced to suspend until a supply is again made available. The transfer of foreign built ships to American register would undoubtedly simplify matters somewhat and the manufacturers are hopeful that a solution of the present difficulty will soon be possible.

The general effect of the war on the metal market will be to weaken the metals which we export and strengthen those which we import, and while the balance of production and consumption will be temporarily disturbed, it is to be hoped that in the readjustment which is to follow mining will not experience the reverses anticipated in some quarters and the present situation will soon be replaced by a stability of markets and prices.

THE INDUSTRY OF THE WITWATERSRAND

By T. A. Rickard

The economic relation of the Rand mining industry to the Union of South Africa is made vividly clear by a recent report of the Dominions Royal Commission, which was appointed by the British Parliament to inquire into "the natural resources, trade, and legislation of certain portions of His Majesty's dominions." This Commission has just returned from a visit to South Africa, where voluminous evidence was taken. That evidence proves that the Union of South Africa is unique among civilized countries in the extent of its dependence upon the produce of its mines for its purchases of imported goods. Of the revenues of the Union, by direct and indirect taxation, 60 per cent comes from the mining industry; of this 60 per cent, fully three-quarters, or 45 per cent of the total revenue, is drawn from the gold-mining industry in the Transvaal. Out of a total Government revenue amounting to $135,000,000 derived from taxation and railway receipts, the Witwatersrand contributes $60,000,000. This last sum compares with $40,000,000 paid to the shareholders in the mining companies operating the mines, and with $40,000,000 paid to the white employees at these mines. Thus the financial interest of the Union Government is 50 per cent greater than that of either the shareholders or the white employees. These facts, thus emphasized, suggest that the purchasing power of South Africa is peculiarly dependent on the produce of its mines, and that there is urgent need to assist the scientific development of agricultural resources to take the place of the mineral wealth, which is essentially a wasting asset. The Commission, however, concludes wisely that the most immediate problem is the efficient development of the assured mineral resources. Coal exists extensively, and may prove of great value in the exploitation of known iron deposits. The diamond mines are yielding about $56,000,000 per annum, so that the Union produces about 80 per cent of the world's supply of this precious stone. This produce is important, but the basic industry of the country is gold mining. Within 30 years the Transvaal has contributed $2,000,000,000 to the world's stock of gold, and at the present time it is responsible for 40 per cent of the world's total output. The salient feature of this prolific production is the fact that the gold is won from a low-grade ore exploited on a narrow margin of profit. At once the cost of labor becomes a crucial consideration. In mining generally that human item represents two-thirds of the total expense of mining. In the Transvaal it is a vital factor to an unusual degree on account of the lack of an adequate supply and the various efforts necessary to import labor from the outside. Of the Chinese experiment, begun in 1904 and ended in 1909, we need only say that it was an economic success but a political failure. It was killed by being made the subject of a sentimental outcry in England. Of the white workers, from Europe, America, and Australia, it is fair to state that they have proved unsatisfactory, their duty as supervisors over the natives having led not only to gradual inefficiency but to political agitation, terminating in a murderous riot. The natives in the Transvaal are quite insufficient for the great industry of the Rand; they have been recruited from all over South Africa, and have been taught to do the work required. But they are nomadic and uncertain; they migrate to their homes periodically; they cease from labor (like their white associates) when they have made enough money; their needs are small, therefore they are able to retire to their kraals soon after they have learned to do their work well. Their wages have increased steadily, largely by reason of the competition between mines, now abated by joint recruiting. The labor factor has pressed upon the managers increasingly. Taking the capacity of two white workers as equal to that of three natives, it is estimated that if the natives at their present cost of 75 cents per shift had to be replaced by whites at $2.50, this being the possible minimum, out of the 52 productive mines, one-half would cease to be profitable. If the whites were to receive $3 per shift, this being the rate current in Australia and America, then out of the 52 mines only 17 could continue in operation. The cost of 75 cents per native includes wages, food, housing, and recruiting. In 1913 a sum of $60,000,000 was paid in salaries and wages by the mining companies of the Rand. The white employee, excluding the technical and clerical staff, received an average of $1580 per annum, while the native received $150, allowing $50 for board and lodging. Meanwhile white labor has become inefficient and unruly. The idea of using only white men has been followed by the proposal to remove the color bar, thereby permitting intelligent natives to act as supervisors. As the native is as much an economic asset of the country as the golden ore itself, it appears a sound proposal. The future of the industry must depend upon the training of the native, with concurrent discipline, so that excessive demands may be checked. It is a reasonable expectation that the wants of the Kaffir will increase as he becomes 'civilized' and that his new needs will drive him to learn how to earn more money by greater efficiency.

In order to obtain data concerning the probable future of the industry, the Chamber of Mines recently commissioned four engineers to prepare a report. They found that 550,000,000 tons of ore were available in the producing mines, which are now crushing at the rate of 28,000,000 tons per annum; this rate, it is believed, can be maintained for five years, after which the annual output is expected to decrease at such a rate that in 1930 it will have fallen to one-half, or 14,000,000 tons per annum. This general estimate assumes no decrease in cost; but it does assume that the remaining undeveloped ground down to a vertical depth of 7500 feet will yield ore of a tonnage and grade equal to that of the last 1000 feet in the respective mines. No allowance is made for a flattening of the lode or an impoverishment of the

ore, although both are likely. Mr. R. N. Kotzé, the Government Mining Engineer, estimates that by 1924 twenty-five mines now producing $50,000,000 annually will have been exhausted; by 1934 a further 13 mines, now producing $52,500,000, will be compulsorily idle; and by 1944 nine more, now yielding $37,500,000, will have ceased operations. Thus, he estimates that within 30 years the Rand's output of gold will have fallen from $180,000,000 to $40,000,000 per annum. It only remains to say concerning these estimates that the industry will not contract as rapidly as the gold production, for the tonnage will diminish much less slowly than the yield per ton and large-scale operations will be maintained long after the shareholders will have ceased to derive benefit therefrom. This is the story of all big mining districts, in which mining performs a beneficent economic function to the community and to the state long after the mine owner has ceased to be enriched thereby.

There remain possibilities. Large undeveloped areas of gold-bearing property are known to exist on the outskirts of the tracts already exploited. Mr. Kotzé estimates that 114,000 claims remain intact; out of these 31,400 may prove to be profitable ground. This unexploited area should contain 600,000,000 tons, or about as much possible ore as is estimated to remain in the present producing mines. Thus to the 230,000,000 tons of ore extracted to the end of 1913, we may add 550,000,000 in the developed mines, and 600,000,000 in the undeveloped area, making altogether 1380 million tons as the ultimate total production of the Rand. While the profit to the shareholders from the 1100 million tons may not equal that derived from the 230 million tons already crushed, it is certain that to the state, and to the community immediately dependent on the mines, it will prove the mainstay of another generation at least.

To those living in South Africa it may appear immaterial whether a particular mine is operated at a profit or not, so long as it continues to employ workmen and consume supplies. Indeed, the money that goes out of the country to absentee shareholders is regarded as an economic loss. This, of course, is a one-eyed way of looking at the problem. The government's profit-tax is diminished and the incentive to open new mines is checked. Hence has come the idea that all the mines should be consolidated into one vast enterprise, to be operated either by the Government itself or by an amalgamation of the existing companies. Such a step would minimize competition for labor and for capital, because the individual mines or companies would be merged in the one super-mining unit. The total capital involved, including debentures, would be about $450,000,000, as compared with the United States Steel Corporation, capitalized at $900,000,000, the Canadian Pacific Railroad, at $800,000,000, and the Pennsylvania Railroad, at $640,000,000, not to mention a half dozen others in America involving at least as much money as the sum representing the capitalization of the Rand; with this difference, however, that a mine is a wasting asset and a railroad is not. The advantages of such a consolidation are obvious, namely, the reduction of overhead expense, the cessation of competition for labor, the facilitation of collective bargaining between labor and capital, the unification of technical effort toward improved mining and metallurgical methods, and the extinction of numerous counters for gambling by the substitution of one real investment. The objections are less obvious; the diminution of individual effort as between members of different staffs, the creation of a power that would overshadow the state itself, and the lack of men of calibre big enough to manage so huge an enterprise. As to the last, it is fairly clear that the combinations already effected, such as the East Rand Proprietary, Randfontein Central, and Crown Mines have already taxed the ability of their managers. The Crown Mines has met the demand for a wide grasp of affairs, but the other two amalgamations have made repeated blunders, due to the fact that super-mining undertakings are easier to create than the super-men to run them efficiently. That, to our mind, is the chief obstacle. It may also be suggested that a consolidation of all the companies would lead inevitably to a de-watering of the shares, for the merging of interests would deprive the shares of their purely speculative value and pull them down to the dreary basis of a quiet investment. That would mean an immediate and heavy loss to the present shareholders, who now have the benefit of a quotation which is enhanced by the speculative feature.

The dewatering will come in the course of events, of course, but it will come so slowly as to permit the loss to be widely distributed. On the other hand, the interest of the Government being already so large, it seems a relatively easy step to further participation. To the Government of South Africa it is desirable to perpetuate this basic industry long after it has ceased to interest the shareholder or the laborer, of whom the first is a non-resident and the second migratory. Undoubtedly the waning of speculative interest will enhance the industrial importance of the Rand to South Africa, and warrant the Government in devising methods whereby the continuity of operations can be safeguarded. The report of the Royal Commission suggests the employment of a world-wide authority, or authorities, on mining matters with a view to obtaining reliable advice, the cost of which would be insignificant compared to the interests involved. A beginning has been made in the employment of Surgeon-General W. G. Gorgas to report on sanitary conditions, and in the retaining of four engineers to assist the Economic Commission. In both instances, the result was highly satisfactory. Assuredly the worst of all waste is the waste of experience. The modern world is remarkable for nothing more than the ability to enlist the help of specialists from every department of human progress. In the Transvaal the economic relation of a special industry to the welfare of the state is so clearly defined as to offer unusual scope for wise treatment.

Origin of the Sudbury Ore Deposits

By STUART ST. CLAIR

No attempt will be made to outline the general geology of the Sudbury district for such information regarding the region has already been published in reports by A. P. Coleman[1], of the Ontario Bureau of Mines, and A. E. Barlow[2], of the Canadian Geological Survey. The discussion in this paper is limited to a consideration of the methods of occurrence and origin of these most interesting sulphide deposits.

CREIGHTON PIT AT COPPER CLIFF, SHOWING OREBODY FROM FOOT-WALL TO HANGING. THE LOOSE ROCK IS MAINLY FROM SLIDES OF THE HANGING WALL.

A resumé of the two views held in regard to the origin of the Sudbury ore deposits may be briefly stated as follows: (1) that the sulphides are primarily of igneous origin, having separated from a molten norite magma by a slow process of differentiation, the ores having segregated at the bottom of the eruptive and at the margin of a synclinal basin in obedience to the laws of magmatic solutions; (2) that the sulphides are entirely of secondary origin, having been deposited along the brecciated margin of the eruptive by aqueous solutions. The sulphides replaced the rock and also acted as a cement, the ore-bearing solutions having been introduced some time after the intrusive had cooled and had been fractured.

All geologists who have advocated the igneous theory concede that there has been solution and redeposition subsequent to the formation of the ores, resulting gen-

[1]Coleman, A. P., 'The Sudbury Nickel Field.' Ontario Bureau of Mines, 1905, Vol. 14, Pt. 3.

[2]Barlow, A. E., 'Origin, Geological Relations, and Composition of the Nickel and Copper Deposits of the Sudbury District.' Can. Geol. Sur., Vol. 14, Pt. H, 1904. Revised and reprinted in 1907.

erally in enrichment of the sulphides and alteration of the original norite rock; that the greatest amount of such alteration has taken place in the 'offset' deposits and that many of the marginal deposits remain today nearly as they were formed, very little change having taken place through aqueous agencies since the time of formation. On the other hand, the advocates of a secondary origin for these sulphide deposits fail to recognize any factor other than circulating waters for their deposition. The men who have done the most detailed geological work in the region are A. E. Barlow and A. P. Coleman. Both are strong advocates of the igneous theory of origin for the orebodies. Their conclusions are based principally upon field evidence. Opposed to their views, and a strong advocate of an aqueous origin for the sulphide deposits, is C. W. Dickson. His conclusions are based principally upon laboratory study of polished surfaces of the ores.

Dickson's Studies

The metallographic methods used by Dickson are intensely interesting, but they show only the present condition of the ores and not necessarily the primary conditions under which the sulphides were formed. In his paper Dickson clearly and strongly presents his arguments to prove the secondary character of the ores, but that conclusions based principally upon laboratory studies may lead to error in solving the origin of the Sudbury ores, is forcibly expressed by Coleman[3]. He says, "Dickson seems to have been singularly unfortunate in the choice of his material for study since he has selected almost without exception the brecciated rock material enclosed in the ore, and judging from his photomicrographs and descriptions, has not studied the opposite phase in which the norite is thickly speckled with the ore particles. Many of his examples are from 'offset' deposits and naturally enough for one who had but a short time for field work in the region, he does not distinguish their characters from those of the marginal deposits, which point more clearly to an origin from the molten norite."

The brecciation of the contact of the nickel-eruptive and the country rock, which consists of greenstones, granite, gneiss, and other rocks, is as one would expect as a result of an igneous intrusion. The deep-seated magma spreading out beneath the overlying Animikean sediments would have to stope its way, and many fragments of the intruded rocks would be broken off, some probably being assimilated in the norite magma. The enclosed rock fragments are both angular and rounded, the latter probably being the earlier fragments broken off, while the former may be referred to stoping action of a later stage when the magma had lost much of its heat and could no longer fuse the edges of the fragments.

The orebodies are found in intimate relation with the norite, and this association is so persistent that one is forced to conclude that there must be some genetic relation between the sulphides and the norite magma. The orebodies occur at the margin of the eruptive rock and are of finer grain immediately at the contact than at some distance away. The rock in immediate association with the ore is much more basic in composition and finer in texture than the rock farther removed from the contact. As one proceeds from the margin toward the inner basin, the eruptive rock gradually becomes more acid and coarser grained until the norite has changed to micropegmatite. At the same time the sulphides, which often occur in masses at the basic edge, change to pyrrhotite-norite with the sulphides disseminated throughout the rock. This in turn grades insensibly into norite practically free from sulphides, and in less than a mile from the basic edge of the southern range thin sections, in my collection, show no sulphides at all in the eruptive rock. The transition between the normal norite and the pyrrhotite-norite furnishes unmistakable evidence that the sulphides were formed during the cooling and crystallization of the norite magma. The norite is unquestionably the original source of the ore.

Just when the synclinal basin was formed is unknown, but more evidence points to the sinking of the Archean basement and consequently the upper sediments into the space formerly occupied by the magma during the time of eruption and during its slow cooling than to formation after the magma had solidified. From a consideration of this structure, the abrupt change from massive sulphides to barren country rock is as would be expected in the case of segregation of the orebodies from a liquid magma. Through fractional crystallization, gravity, convection currents, and probably other factors, the heavy parts of the magma would settle to the bottom, and the basic constituents would collect at the cooler parts, which would be at the contacts. The contemporaneous or subsequent formation of the synclinal basin, and the long period of erosion to which the edges were subjected, would cause just such structural conditions and ore occurrences as are found in the field today.

Basic Border and Acid Core

The differentiation of magmas into a basic border zone and an acid core has been recognized and studied in many cases. The factors producing this separation and concentration are not agreed upon by petrologists, but that such conditions obtain in solidifying magmas is indisputable. The Sudbury laccolithic intrusion was subjected to this process of differentiation. If the magma separated into diverse parts, the acid being concentrated at the centre and the basic segregating in the outer portions, would it not be reasonable to suppose that the heavy sulphides in a like manner separated from the basic portion of the magma? A magma rich in dissolved metals and sulphur is all that would have to be presupposed.

The conditions under which the Sudbury laccolithic intrusion began to differentiate into an acid and a basic phase were those of considerable depth. The intrusion spread out between the Archean rocks below the Animi-

[3]Coleman, A. P., 'The Sudbury Nickel Field.' Ontario Bureau Mines, 1905, Vol. 14, Pt. 3.

kean sediments above. These sediments, it is estimated, had a thickness of nearly two miles, and, at such depth and under such conditions of pressure, the magma would cool very slowly, and there would be ample time for a complete separation. In such a case gravity would undoubtedly be an important factor in the settling of the heavy sulphides to the bottom and the collecting of the lighter acidic constituents at the top. The action of fluid mineralizers, according to Michel Levy's theory, would aid in the concentration of the lighter or more acid substances above the basic below. The basic constituents would also tend to concentrate at the edges of the intrusive sheet, probably in accordance with Soret's principle, which states, "If different portions of a homogeneous solution of a salt are kept at different temperatures for any considerable length of time, the salt will concentrate in the cooler portion of the solution." Both Vogt and Kemp favor this principle in the differentiation of a magma, and although many scientists have discarded this principle when applied to magmas, on the basis that such a process of molecular diffusion would require too long a time, it is considered to be a possible factor. Under such conditions of depth and of temperature as existed in the case of the Sudbury laccolith, the time required for differentiation by Soret's principle may not be a very serious objection to its application as one of the factors of differentiation of the Sudbury ores.

Primary Ores and Magmatic Waters

The magmatic waters which usually follow extensive volcanism were, I think, of primary importance in the concentration of the large orebodies. After the sulphides had undergone a process of segregation by gravity, and the magma was still in a molten condition, such concentrating action by the magmatic waters would be simply one of the factors of the magmatic differentiation process, and could not be classed as 'after action.' There was, very probably, after action also that caused further concentration of the ores by solution and redeposition in fractures produced by cooling and contraction of the magma, and probably by a certain degree of further settling of the synclinal basin. The action of the magmatic waters during cooling, which would cause a greater fluidity of the basic portion at the margin, would aid in explaining the great distances to which some of the apophyses extend into the country rock.

The richest deposits, many of which are almost pure sulphides, are found in embayments which extend into the Archean substratum. The most important deposit of this character so far worked is at the Creighton mine. At this point an enormous body of sulphides rich in nickel and copper has been opened up. This deposit seems to afford an excellent example of concentration due primarily to gravity, the heavy sulphides having evidently settled into the depression and solidified as pure ore. That aqueous alterations and enrichment were of great importance in concentration seems hardly possible, as the ore and rocks are singularly free from fracturing.

Another factor which would probably aid in the differentiation of the magma is redistribution by convection currents, resulting from unequal temperatures. The magma spreading out between the rocks would become cooler at the points of contact with the country rock. The upper and outer edges would, therefore, be the coolest parts of the sheet, the outer margin especially, and a circulation would start between these points and the highly heated centre. This process, combined with chemical affinity, would possibly constitute a factor well worth considering in the discussion of the relative importance of the various factors in connection with the magmatic differentiation of the Sudbury ores.

Paragenesis of Sulphides

The paragenesis of the sulphides is largely a matter of speculation, but a few orders of crystallization will be given. According to Fournet, in a molten magma of silicates in which sulphur has been dissolved, the sulphur shows affinity for the metals in the following order: copper, nickel, cobalt, iron, tin, zinc, lead, silver, antimony, and arsenic. From this one would expect to find that the ore minerals had crystallized in the following order: chalcopyrite, pentlandite, and pyrrhotite. The copper, nickel, and cobalt sulphides, which constitute but a small part when compared with the amount of pyrrhotite, should be found concentrated in the pyrrhotite, and in many cases such relations are found, but more often the reverse occurs. In other places the intimate relation between the sulphides themselves and with the norite, points to a nearly contemporaneous solidification. Again, the relations show that the pyrrhotite antedated the pentlandite and the chalcopyrite since the pyrrhotite is often surrounded by the chalcopyrite. In consideration of the last described condition of occurrence it would seem that the chief factors controlling the solidification of the metals were the viscosity of the magma and the fusing points of the sulphides.

Effect of Mass Action

Another factor which must be considered in the crystallization of the Sudbury intrusive is the law governing mass-action. Mass-action as recognized operates to produce many irregularities in the crystallization of the magma. The chemical equilibrium of a complex solution is very unstable and is easily unbalanced by such influences as temperature and concentration. To what extent mass-action influenced the order of crystallization in this magma cannot be stated, but it may have reversed Fournet's order to begin with, and later the magma may have reached the proportions of a eutectiferous solution, and subsequently crystallized according to the laws governing such a solution. Since the pyrrhotite is so much more abundant than the other sulphides, this law of mass-action may have been of primary importance in determining the order of crystallization of the ore minerals.

The metallographic studies of the orebodies by Camp-

bell and Knight[4] showed the order of formation of the sulphides to be, 1, pyrrhotite; 2, pentlandite; 3, chalcopyrite. But their work cannot be used in determining the order of primary deposition of the ores for their specimens show three periods of deposition of the sulphides, two at least of which are secondary since they occur in veins and along fractures in the pyrrhotite.

The men who favor most strongly the aqueous origin of the ores consider that there may have been a slight primary concentration of the metals with the intrusion of norite, but they consider such a concentration unimportant. Dickson does not attribute the source of the metals to the norite, but favors a more distant source. The metals it is thought may probably have been minutely disseminated in the rocks through which the depositing solutions passed.

Ores from the Eruptives

However, from a consideration of all the facts it seems clear that the source of the ore must be sought within the eruptive itself. It will be remembered that, (1) sulphides are known to be primary rock-forming minerals; (2) magmas tend to differentiate into chemically and mineralogically diverse parts, the acid rocks forming the inner zone or core, the basic rocks the outer or border zone, this splitting up being due to fractional crystallization, action of mineralizers, variations in temperature and pressure, convection, or a combination of any or all of these and probably many other factors; (3) the sulphides are found at the borders of the basic border-zone, in embayments, and disseminated through the norite, the amount of ore being inversely proportional to the distance from the basic edge; (4) the sulphides are very intimately associated with the norite of the basin type, and with norite only; (5) the conditions were those of great heat and pressure, and there was present in all probability a large amount of magmatic water; (6) the ores throughout the district are remarkably uniform, consisting as they do of pyrrhotite, chalcopyrite, and pentlandite. If the ores had been formed by deposition from aqueous solutions, it seems hardly possible that such uniformity should exist. Replacement minerals such as are found in other copper and nickel fields are almost entirely lacking, and there is a marked absence of crystals of metallic minerals and drusy-covered cavities so typical of water action; (7) in some places the rocks close to the orebodies are greatly altered, the pyroxene having changed to hornblende. Such a condition would show secondary aqueous action. Again, in many places the rocks close to the orebodies show no alteration at all. Such a condition would show that the ores could not have been formed on such an extensive scale, as they are at present found, by aqueous solutions. Many specimens obtained in the immediate vicinity of the various mines show fresh and unaltered material. Some containing as much as 10% sulphides have undergone so little metamorphism as to permit of the positive identification of all the prevailing minerals, including hypersthene, enstatite, diallage, olivine, and labradorite. Sulphides frequently occur in portions of the norite which have suffered little or no dynamic metamorphism, and practically no hydro-chemical alterations.

[4]Campbell and Knight, 'On the Microstructure of Nickeliferous Pyrrhotite.' *Econ. Geol.*, Vol. 2, p. 350.

Conclusions

In drawing a conclusion as to the origin of the Sudbury ores, precedence must be given to the views of such men as Coleman, Barlow, and others who have studied deposits of copper-nickel sulphides both practically and theoretically, the relations shown in the field and the associations found to exist between ore and rock from laboratory studies. These men have shown in their reports evidence to uphold the igneous theory, and most other geologists who have studied the deposits in the field have agreed with these pioneers of the theory of ore deposits formed by magmatic segregation. While much credit must be given to Dickson for his attempt to prove an aqueous origin for the ores, consideration of all the facts seems to forbid the belief that these ore deposits could have been formed primarily by any action other than a direct segregation from a molten magma.

Large Platinum Nuggets

Three interesting platinum nuggets of remarkable size recently passed into the possession of a large platinum refiner at Hanau. These nuggets, or 'samorodki,' as they are called in Russia, are great rarities, and were found in the river sand of the Iss, near Nishne-Tagil, in the Ural mountains. They have a total weight of 17.122 kg. or 550 oz., the individual weights being 7.782, 4.775, and 4.565 kg. They are valued at about $25,000. The large nugget was found 25 and the two smaller ones about 20 years ago. Since that time no further pieces of such size have been discovered.

The largest single lump of platinum ore that has ever been found was discovered about 100 years ago in the same vicinity, and is still to be seen, as the rarest natural curiosity of its kind, in the Demidoff Museum, St. Petersburg. The largest of the three nuggets referred to is, therefore, probably the second largest that has come to light so far. The nuggets contain 86.5% of pure platinum, about 3% iridium, and small quantities of other metals. It may be thought that in localities where such large and heavy lumps of pure platinum occur there should be frequent finds of valuable pieces, but this is not the case. Even pieces weighing 20 to 50 grams are rarely found.—*The Jewelers' Circular.*

A new 'centipede' locomotive, weighing 410 tons, having 24 driving wheels, was recently tested on the Erie railroad. A train of 250 cars of coal, the whole weighing 21,000 tons, was pulled by this engine for 40 miles at 15 miles per hour. This is a world's record, and 10,000 tons over the best previous performance.

Titration Results in Cyanidation

By A. W. ALLEN

The accompanying diagrams are illustrative of a number of tests which were made for the purpose of obtaining a better understanding of the distribution, and also the loss, of cyanide at various points in a 'milling in cyanide' plant, and in the hope that the results might throw some light on the question of the disappearance of zinc from plant solutions. The tests were made by the method described in the *Mining and Scientific Press*, September 20, 1913. Twelve separate samples in all were tested, the complete series of estimations taking an hour and a quarter. The latter point is mentioned since in some quarters it is thought that solution control by scientific methods is too lengthy and tedious an operation to merit the attention it undoubtedly deserves. Stock solution used at various points in the mill was only tested for once. It was assumed that no material alteration in composition would occur during conveyance in piping.

In practice lime is added at the batteries, but the addition was temporarily suspended while these samples were being taken. Unnecessary complications in solution composition were thus avoided. The addition of make-up water was also temporarily suspended for a similar reason.

Fig. 1 gives free cyanide content. It is noticeable that no reduction in free cyanide content occurs in the solution passing through the batteries. This is due, in all probability, to the high alkalinity being maintained, coupled with the fact that the flow of solution through the batteries is so rapid and the dilution so high that no appreciable alteration is likely to be recognized by the ordinary methods of testing. There is a loss of free cyanide in the tube-mills and also in the agitation vats. This might be expected. The greatest loss, however, occurs in the zinc-boxes as a result of the necessary maintenance of an ample free cyanide content to ensure satisfactory precipitation. Whether this disappearance of free cyanide means a total loss of all the contained cyanogen is very doubtful. It is probable that, as regards further solution of metal, the double cyanide formed is at least partly available. As regards subsequent precipitation with zinc it is wholly unavailable.

Fig. 2 deals with the protective alkali content, which is estimated in terms of potassium hydrate. The results are, therefore, higher than they would be if recorded in terms of sodium hydrate.

It is noticeable that there is a decrease in protective

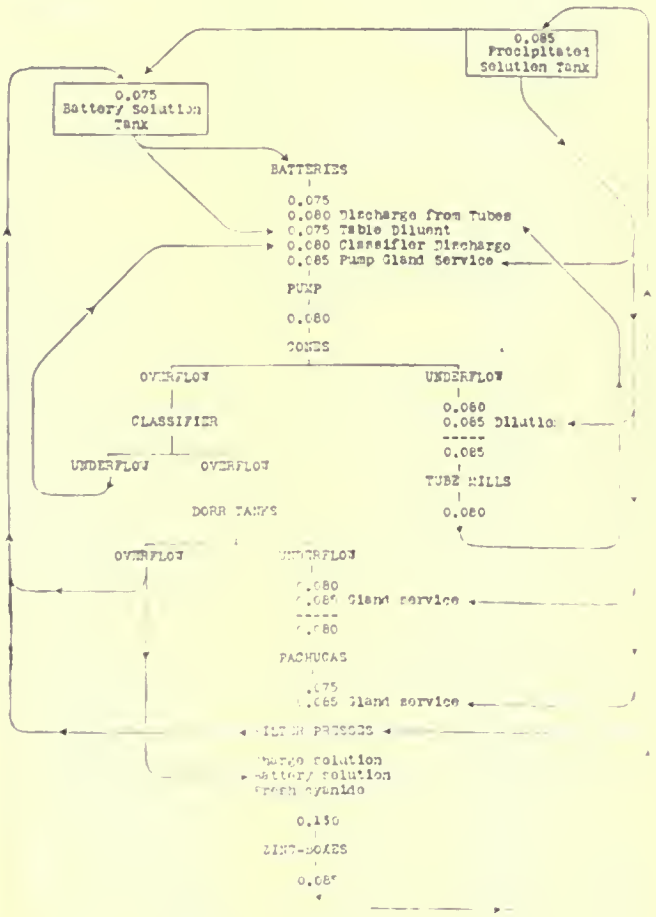

Fig. 1. FREE CYANIDE AS KCN.

Fig. 2. PROTECTIVE ALKALINITY AS KOH.

alkalinity in the batteries, which is indicative of an acid reaction in the ore. A further reduction in alkalinity occurs in the tube-mills where the ore is still further reduced and additional acidity exposed. There is a further reduction in alkalinity as the pulp passes to the filtration department, a somewhat inexplicable drop occurring after the ground pulp comes in contact with precipitated solution in the pumps elevating to the Pachuca vats. There is a considerable rise in protective alkalinity after zinc precipitation due to the solution of

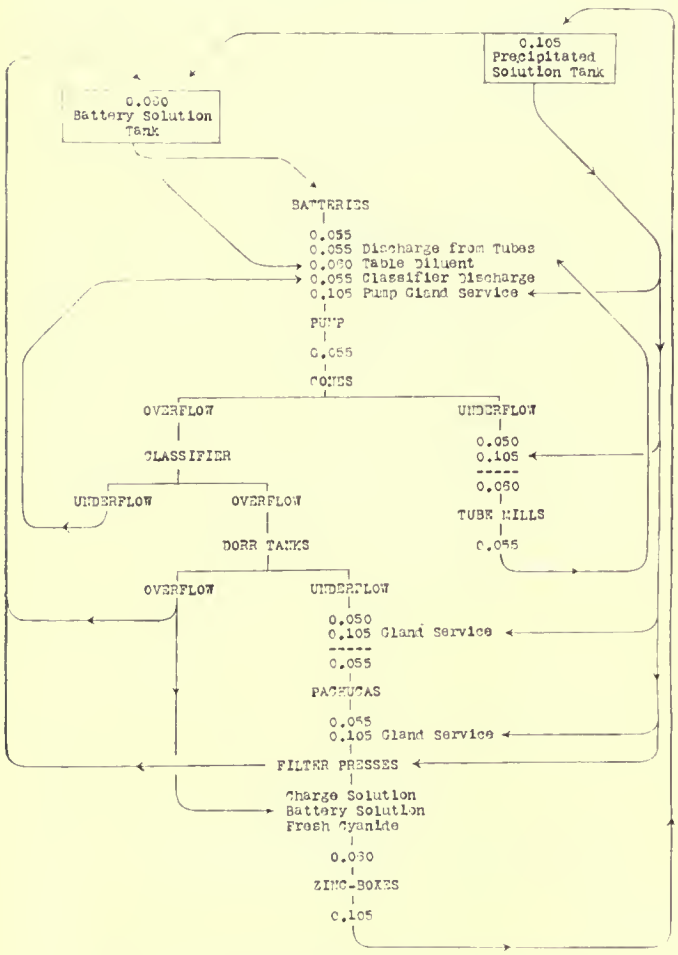

FIG. 3. ZINC DOUBLE CYANIDE IN TERMS OF KCN.

excess zinc, and the consequent formation of free caustic alkali.

Fig. 3 gives details of the content of zinc double cyanide, in terms of potassium cyanide. It is interesting to note that there is a loss of double cyanide, as indicated by this method of testing, from the time the reduction of the ore commences until it is completed. It may therefore be put forward as a tentative explanation that the double cyanide is locally decomposed by the acidity of the ore resulting in the formation of hydrocyanic acid, and an insoluble zinc cyanide. This would involve an ultimate loss of zinc and cyanogen. It may be further assumed that the hydrocyanic acid so liberated might attack the gold forming hydrogen-gold-cyanide which in its turn might be acted on by the free alkali present to result in the formation of the normal potassium-gold-cyanide compound. This explanation is not in accord with the results of laboratory experiments and is opposed to the generally accepted ideas with regard to the stability of hydrocyanic acid in the presence of excess alkali. It cannot be used to account for the loss of zinc from plant solutions in the case where the ore is milled in alkaline water. In the present instance it is the only explanation that suggests itself.

The addition of zinc to the solution is indicated by a considerable rise in double cyanide content after zinc precipitation.

Tin Mining at the Briseis, Tasmania

As explained in the Company's report, to be published in this journal later, operations at this property consist in removing a hard and sometimes decomposed basalt overburden, and sluicing the layers of tin drift beneath. The work generally presents some difficulties, one being the tailing disposal and the proximity of the Ringarooma river, which is now being diverted. In 1913 the following was done:

Briseis drift and overburden sluiced, cubic yards	275,000
Black tin recovered, tons (74.6% metal)	464.1
Average black tin, pounds per yard	3.78
Ringarooma or upper drift sluiced, cubic yards	286,000
Black tin recovered, tons	38.9
Average black tin, pounds per yard	0.3
Ringarooma overburden removed, cubic yards	91,900
Total ground moved, cubic yards	652,900
Total black tin output, tons (74.6% metal)	515

Cost of recovering black tin and dressing it ready for smelters was as follows:

	Per ton of black tin.
Sluicing, cleaning bottom, overburden cost, etc.	$53.85
Pipes, ditches, elevators, etc.	25.90
Clean-up, dressing, etc.	6.70
Electric light	4.80
Head ditches upkeep	12.96
Stores, timbers, explosives	2.06
Dumping overburden, etc.	40.46
Salaries and office	22.80
Total	$169.53

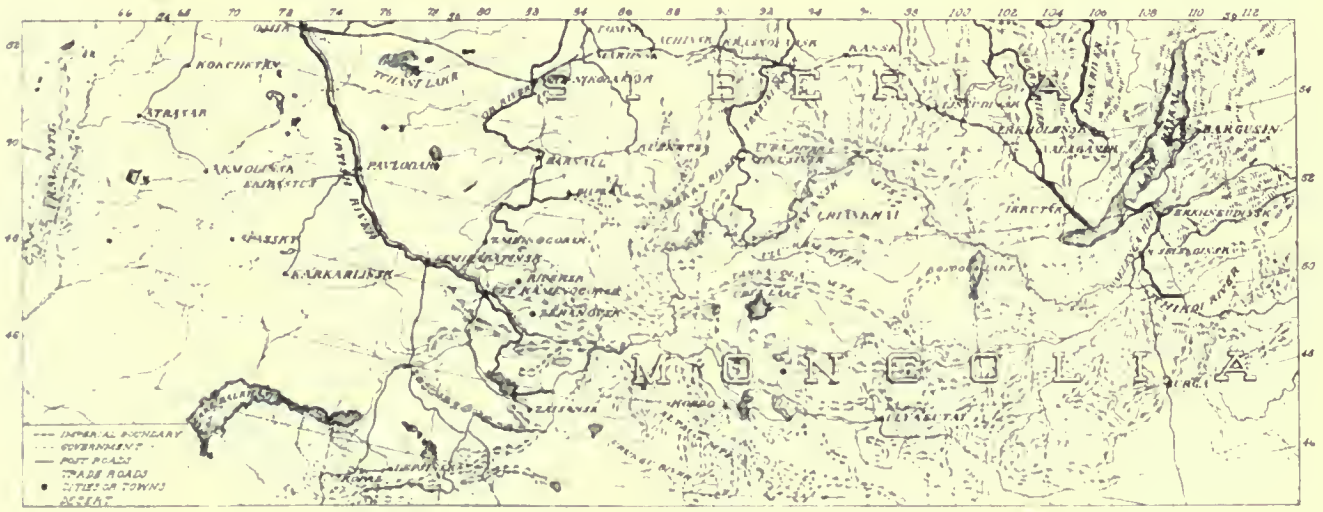
The cost per ton of metal was $233.50, and the price received for the metal was $875.40 per ton. To this cost of $233.50, should be added $38.60 for freight, smelting, etc., making a total of $272.10 per ton of metal. Moving the hard columnar basalt overburden cost 34.67c. per cubic yard. From the sluice-boxes was recovered 56 oz. of gold worth $760.

COAL MINED IN KENTUCKY in 1913 was 19,616,600 short tons, valued at $20,516,749, according to Edward W. Parker, of the U. S. Geological Survey. The increase over 1912 in quantity mined amounted to 3,126,079 short tons, or 19%, and the value increased $3,662,542, or 21.7%. The number of men employed in the coal mines increased from 24,304 in 1912 to 26,332 in 1913, and the average working time from 201 to 212 days. The average production by each man employed was 745 tons in 1913, against 679 tons in 1912 and 640 tons in 1911.

Gold Mining on the Amur

By W. H. SHOCKLEY

*It is perfectly true that "Siberian butter gives twice as much gold as Siberian gold mines," and equally true that other industries—coal, petroleum, cotton, iron—may have, from a governmental standpoint, no less importance than the production of gold. Nevertheless, for the economic life of the region, especially for eastern Siberia, gold-mining plays a very important rôle. A large portion of the gold output remains in the country for the purchase of supplies and labor, and a portion of the profit is employed for the development of trade and industry. As yet this important industry is only in the preliminary stage, and, with the exception of a small amount of vein gold, produced by work-



GOLD MINING REGIONS ALONG THE SIBERIA-MONGOLIA BORDER.

ing the most important deposits on an insignificant scale, only alluvial gold is produced.

According to official statistics, the production of gold in the Amur and the Transbaikal was: 1905, 320,321 oz.; 1906, 349,703 oz.; 1907, 380,282 oz.; 1908, 406,048 oz.; 1909, 422,448 oz. But A. N. Mitinsky, the representative of the Minister of Trade and Industry, says that "the greater part of the statistics regarding gold mining is questionable, because of the incomplete registration of the gold; the figures do not correspond with the truth, even in the case of honest operators who do not report a smaller amount of gold than is won, for the purpose of paying a smaller royalty or a less tax on the profits." In a word, "there are no accurate statistics of such an easily concealed and universally desired metal as gold, and cannot be, and for this reason the analysis of the gold production must be carried on rather qualitatively than quantitatively."

The greater part of the gold deposits of the Transbaikal, in itself so rich in minerals, is in the hands of private *concessionaires* of the Cabinet of the Czar.

The legal situation of Transbaikal in relation to gold is complicated: the western, and poorest portion, is open; but the richer eastern portion is closed to private operators. The Cabinet has exclusive right to the precious metals in Transbaikal; in the part that is open to private operators it has the same right by law as ordinary individuals, but at the same time it may close separate districts by special instructions. On all the gold produced in Transbaikal a tax of 5% is levied for use of the Cabinet. Besides this, the Cabinet takes a further tax of about 20 cents per acre for each mining claim.

In the area closed to private operators (the Cabinet gives the right of working gold mines to special *concessionaires*), the largest holder is the Nerchinsk Gold Co., Ltd. Although trading in gold is forbidden in the Transbaikal, it is only by a fortunate accident that poachers can be caught; for it is impossible to stop trading in gold from other districts open to its circulation, and it is practically impossible to prove that the gold comes from a designated mine in Transbaikal. According to Mitinsky, only the extension of the free trade in gold throughout the Transbaikal and the replacing of the income from the 5% tax by some other income for the use of the Cabinet can radically clear up the demoralized 'poacher atmosphere.' This is the method by which other portions of Russia were freed.

In that part of the Transbaikal that is open to private mining there are four sorts of land titles: (1) Cabinet, (2) non-Russian natives, (3) peasant, (4) Cossack. On the open Cabinet lands in the western portion, everyone can mine for gold in exactly the same manner as on the open Cabinet lands in the rest of Russia. For obtaining mines under the other categories it is essen-

*Translated from *Zoloto i Platina*, Jan. 15, 1914.

tial for the would-be miner to come to an arrangement with the owner of the ground; such agreement must be confirmed by the local authority: by the agent of the natives, the administration of the Cossacks, and the special council of the peasants. The development of gold mining is much retarded because there is no normal price for the surface rights. This absence of a normal price repels responsible capitalists, and it is highly desirable that such normal price should be established.

Outside of the Cabinet, practically the only large companies working in the Transbaikal are the Russian Gold Mining Co. and the Nechinsk Gold Co., Ltd., which companies are working concessions. The other private operators are financially weak. Up to the present, alluvials are worked by preference; the richest deposits have already been exhausted, and, by official statistics, the tenor of the ground is now about 6c. per cubic yard. This is the value on which the taxes to the Cabinet are paid; the real value is about 15c. Vein gold mining is in a bad way, for not a single mine has been properly developed.

Cabinet Operations

The principal operator is the Cabinet itself; according to the reports, its production in the Nerchinsk district was:

	1907.	1908.	1909.
Total output, troy oz....	63,455	66,302	80,236
Value $1,155,174		$1,210,123	$1,449,766
Value per ounce	$18.20	$18.25	$18.07

As stated above, there is but little work on the concessions in that part of the Transbaikal that is closed to private miners. The gold obtained from these concessions was, in 1908, $27,500, and in 1909, $86,000. A very small portion of the concessions is worked.

The gold production of the Transbaikal was, in 1907, 28,544 oz., in 1908, 33,416 oz., and in 1909, 47,727 ounces.

The production of vein gold in the western Transbaikal during the three years was only 5727 oz. The 5% tax paid to the Cabinet by miners working without concessions was: 1907, $17,952; 1908, $10,738; and 1909, $7092. Since the receipts of the Cabinet from this 5% tax are so insignificant, it seems superfluous to prove clearly the advantage of its abolition; for this 5% tax, payable in cash, is a restraint on legal gold mining in that part of the region open to gold mining, and is an encouragement to illegal mining, and encourages the flow of gold to China, and thus touches the general interests of the country.

There are very strong hopes of further developing gold mining in this region for the reasons given above, but there is little private exploration. In the eastern Transbaikal the Cabinet spends about $50,000 yearly in prospecting, a sum large in itself but very small in comparison with the extent of the country. The amount of gold which has been fully developed during the last few years is between 236,990 and 289,655 oz. Rich placers assaying 60c. per cubic yard have been opened within the last few years on the Cossack mines: Garimur, Borzya, Kasakovka, and Novotropok, which lie in a comparatively settled country and have been worked for a long time. In the deep virgin forest of eastern Siberia are the renowned penal mines of Kariosk, and, still farther to the north, Gorbichansky. The first of these produced 473,981 oz., and the second 315,987 oz. of gold.

Gold mining has recently begun on the zone of the Amur railway. The gravel here is very rich, and the bed of the river is worked by freezing. At present, in this region, which only a short time ago was practically inaccessible, there is being developed a semi-illegal gold mining, which brings on the market the so-called 'voluntary' gold, which is sent to the Blagovestchensk assay office.

The output of gold during the past few years has increased by legal and illegal working of the Cabinet lands, and also by the extensive employment of Chinese on the partly worked out claims of the Cabinet.

The gold of the Amur is divided into seven classes:

1. Gold produced by means of machinery excavators on the Titova mines on the Jalinda, Aksenta dredge on the Unak, etc., without help of Chinese labor.

2. Company work, preferably by Russian workmen. Five companies produced 79,000 to 92,163 ounces.

3. Working under supervision, systematic working with company machines, but with payment of royalty producing 52,664 to 63,197 ounces.

4. Ordinary leasing work.

5. Working "with regulation," which is the widest spread and is increasing. The holder of a mining claim puts Chinese to work, under their own management, with whatever apparatus they wish, under the condition that they sell him a fixed amount of gold at a fictitiously low price for every Chinese who works.

6. Work "without regulation," whereby the owner of the mine builds a warehouse and allows the Chinese to work as they please, under the condition that they buy not less than a fixed amount of goods per man per month; the price, naturally, being exorbitant.

7. Gold stolen from the first three classes. Included in this is the Chinese gold from the right bank of the Amur. According to the data of the government assay offices, the greater part of the gold received from the district is called 'voluntary.' An insignificant part of this is mine gold escaping registration, the greater part being produced by men working under the 'with regulation' system, but of this gold no small part is 'poached' or stolen.

Incidental Profits

The amount of gold won by regular mining diminishes yearly, and the mine owner derives most of his profit from selling goods to the Chinese at high prices or by charging them for the right to work on his claims. Irregular working by hand produces gold cheaper than dredging and mining under legal restrictions. This cheaper production is due to the irregular worker escaping the cost of company administration, taxes, medical care, and also because he handles only pay ground and

disposes of his tailing by covering ground too poor to work and thus avoids expense of transportation. The irregular worker can fairly be compared to a smuggler, and the miner on a large scale with all the advantages of science and machinery to a wholesale merchant.

The thinly settled nature of the country and the consequent expense of bringing in Russian workmen has led to the employment of Chinese. The flood of Chinese was partly caused by the result of the experiment of bringing Chinese to the Crown lands in the Primorsk for the account of the Government. And the destruction of the so-called 'Jeltuginsk Republic' in 1887, led to the flight of experienced Chinese gold miners into Russian territory. The great influx of the Chinese, however, was caused by the building of the Chinese Eastern railway. The movement increased in 1905 and was connected with a general trend of the Chinese from Chefoo to Manchuria. The change in employment is shown by this illustration:

Workmen.	1900.	1909.
Russian	80%	12%
Chinese	11%	87%

After 1905 the Russian movement into Siberia increased, and work in mines could have been carried on by Russian workmen had it not been for the demand for Russians by the Amur railway; for example, the Suchansky coal mines had only 200 Chinese out of 1000 workmen in 1911.

However, Russian workmen are expensive in all parts of the Priamur, for the population is scanty and comparatively wealthy. Chinese, though but little cheaper, are preferred to Russians on account of the many Russian holidays and because, although the Chinese work slower, yet they do not get drunk regularly. In addition, the Chinese, fearing death but slightly, do not demand medical aid.

A fair estimate of labor in Transbaikal is 2000 Russians annually and 25,000 to 30,000 Chinese, coming during the summer months. Mitinsky speaks of the abnormal condition on the Amur railway, where only Russians are allowed to work, but 100 ft. from the roadbed begins the dominion of the Chinese. In 1906 there were 15,000 Chinese in the Amur district; in 1907, 40,000; in 1908, 60,000; and in 1913, more than 120,000.

Living Conditions

Mitinsky gives a picture of the life and work of the Chinese in the mines, which attests their immense capabilities for combination and organization. Their camps are built lengthwise of the mines and contain from 700 to 1200 men; most of them work on leases; a portion are merchants who import Chinese wares. The Chinese gang consists of from 100 to 150 men and acts as a unit. In case of a serious quarrel between the gangs it is difficult to reconcile them. In the winter the Chinese go home.

The working of the Chinese 'with regulation' is very simple. The head of the gang must sell the mine management a stated weight of gold per month at a fixed low price for each man employed; for example, 0.55 oz. at $10.50 per ounce; this practically amounts to paying about $4 per month for each Chinese employed; taking gold at $18 an ounce. The working 'without regulation,' or by the 'warehouse' system, is very attractive to the Chinese, for the goods are sold at a lower price than by the regular mine owner. To render the employment of Russian workmen possible, the illegal 'warehouse-poaching' methods must be changed to hydraulic mining and dredging; this will require capital and science and will not be as easy as selling merchandise.

As it is now, every mine owner has yielded to the seduction of yellow labor, and has been delivered from the need of putting capital and science into his business. But in case of an outbreak of war in the Far East the mining population will find itself entirely under Chinese domination. To combat the influx of Chinese the mining law should be strictly enforced and the complete extraction of gold from the mines insisted on.

In conclusion, it may be said that the future of gold mining in Siberia will be brilliant. In the Amur district alone there is a vast store of gold, a conservative estimate is 145,000,000 oz. of alluvial gold. The Amur province can produce for each of the next hundred years more gold than the entire present annual production of the rest of Russia, which is 1,395,609 ounces.

San Francisco Mint Operations

During July this institution received 306,740 fine ounces gold and 89,485 oz. silver worth a total of $6,390,759. The coinage executed was $2,500,000. Coin, bullion, etc., on hand on July 31 was:

Gold coin	$ 13,058,070.00
Silver coin	61,692,734.20
Nickel coin	25,104.95
Bronze coin	31,130.63
Checking balance, Treasurer United States	2,012,791.15
Gold certificate bars	127,354,014.91
Gold bullion	42,640,396.18
Silver bullion	528,017.35
Total	$247,342,259.37

Gold output of Rhodesia during the first half of 1914 and 1913 is as follows, in fine ounces:

Month.	1914.	1913.
January	59,212	52,455
February	61,748	49,596
March	64,893	61,274
April	70,336	57,295
May	68,983	57,866
June	72,645	56,991

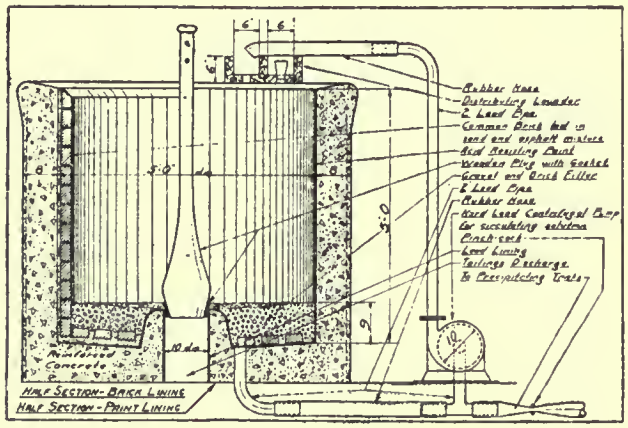
The new mines are now making their yields apparent in the totals.

Gravel mined at the Lena Goldfields property, Siberia, from October 1, 1913, to June 10, 1914, was 558,772 cu. yd., of which 253,477 yd. was washed, yielding 121,316 oz. gold worth £455,946. There were 6987 men employed.

Leaching Experiments on the Ajo Ores—II

By STUART CROASDALE

*Of the two methods recommended [see original paper] for waterproofing concrete, the use of 'Toxement' and by crude oil, the concrete mixed with crude oil appeared to be less attacked by the acid solutions at the end of two months' service than that mixed with Toxement, although the difference was scarcely noticeable. Both methods require a much longer time for the concrete to set than when neither is used. So far as could be observed, the acid-resisting qualities of concrete and plaster prepared with either Toxement or oil were not any better than those of ordinary concrete and cement plaster made with silicious sand and gravel. Acid-resisting paint known as 'R. I. W. No. 89', prepared especially for this work, was of no value whatever in protecting the concrete vats from the 10% sulphuric solutions, the weaker lixiviants in the leaching vats, or the neutralized copper sulphate solutions in the precipitating tanks. Asphalt applied hot or as a paint was likewise useless as a protective covering for the cement plaster under any of the above conditions. One difficulty in retaining this on the walls of the vats was the high temperature of the water used for washing the ore, which averaged 100°F. or more.



STRUCTURE OF VAT USED.

The use of such warm wash water may be criticized and would have been changed under ordinary conditions, but there was a possibility of the water supply coming from hot springs or wells, if developed near the mine, so it was thought best to put the asphalt coverings to the severest test. Besides, a glance at the atmospheric temperatures during the summer months, as given in the beginning of this article, is sufficient to show that even this part of the experimental work required some care in manipulation. Asphalt that would soften and run from joints between bricks or from walls under the heat of the sun, might be brittle enough to crack at night and allow the acid solutions to get at the cement behind it.

With the exception of Vat *A*, all the leaching vats, acid, and precipitating tanks may be considered as operated for the entire two months on the cement plaster alone, for at no time did the protective covering last more than 24 to 48 hr. on the leaching vats, and on the acid and precipitating tanks the paint would come off in patches after a few hours' or a few days' exposure to the solutions. At the end of two months the Toxement plaster, ½ in. thick, was disintegrated to the concrete in places on Vat *B*, and the oil-mixed plaster of the same thickness was disintegrated nearly to the concrete on Vat *C*. In the acid storage tanks both the Toxement and oil-mixed plaster were dissolved in patches by the 10% acid solutions, and the solutions leaked through the 8-in. concrete walls. These holes were patched with ordinary cement and sand plaster and also with neat cement, both of which held the solutions successfully for several weeks. One of the storage tanks was replastered with cement and sand and thoroughly coated with paraffin, which was forced into the plaster with a hot iron. When filled with dilute acid lixiviant, the paraffin came off immediately and was of no value whatever as a protective covering. A plaster, recommended by the Standard Oil Co., was also tried on the acid storage tanks. It was composed, by weight, of 10% litharge, 20% short-fibre asbestos, and 70% sand. These were mixed into a mortar with 40% silicate of soda and applied in the usual manner. This plaster immediately disintegrated on filling the tank with water. The tank was then replastered with the same materials and filled with dilute acid. So long as the plaster remained covered with acid, it was satisfactory protection, but on exposure to air it began to disintegrate and crumble away.

Character of Lining

Some of the leaching vats were plastered with ordinary cement and sand mortar and painted with several coats of crude petroleum. Each application of oil was allowed to soak into the cement and become perfectly dry before another coat was applied. This was done at the close of my experiments and I had no opportunity to test its merits. The brick lining in Vat *A* proved to be very satisfactory. With the exception of where the asphalt was melted from the joints by the hot wash water, no deterioration could be noticed. This was due to the irregular size and shape of the common brick used for the lining and could be avoided by using pressed brick of uniform size which would permit of thin joints. In a large vat the brick would also be laid flat instead of on edge. The sand and asphalt bottoms were entirely

*Extract from a paper to be presented at the Salt Lake meeting of the American Institute of Mining Engineers and printed in the *Bulletin*, August 1914.

satisfactory when they were pressed solid with a heavy hot iron muller like that used in street paving. If this was not done, they were porous and spongy and no protection against the solutions.

As now developed by the limited operation of the experimental plant, ordinary or oil-mixed concrete will be entirely satisfactory for leaching vats, wash water, and neutralized copper sulphate solution tanks. These can be made tight and acid resisting by lining with pressed brick of uniform size, laid in asphalt and backed with hot asphalt poured between the brick and concrete. Vitrified brick would be less porous and preferable if they can be obtained straight and uniform in size. The vats should be plastered inside with cement and sand mortar before putting in the brick lining.

Character of Cement

The cement used in construction work came from the regular run of the mill at El Paso and contained variable amounts of free lime. It is my belief that with cement and other materials containing no free lime, a concrete vat can be built and lined with brick, laid with thin joints of cement and sand mortar, that will be entirely satisfactory for acid leaching. After the bricks soak full of mineral salts, there is very little if any transfusion of the corrosive solutions to the concrete back of the lining, and they form a protective coating for both ore and solutions. Oil-mixed cement plaster will last two or three months without patching or renewal. A brick lining laid in oil-mixed cement mortar would probably last longer than plaster, but the asphalt and brick lining is recommended if it can be held in place.

The cracks that form after construction are the most serious, if not a fatal defect in concrete for leaching vats. These are often so small that they are scarcely noticeable and yet are sufficient to start a leak that is almost impossible to stop, even with asphalt itself. The shape of the vats is immaterial, although for economy of construction and operation a rectangular concrete vat is preferable. The tailing can then be removed from the top, and the bottom of the vat made solid with no openings. The bottoms of the vats should be paved with sand and asphalt, thoroughly pressed down with hot iron mullers or otherwise to make a compact covering. On top of this should be a brick paving laid in asphalt. The storage or acid mixing tanks for the 5 to 10% acid solutions should be made of steel or wood and lined with lead.

Protection of Pumps

The hard-lead centrifugal pumps used for circulating the solutions showed no wear except the steel shafts. It was difficult to keep packing tight enough around the shafts to prevent the leakage of solutions, and at the same time not crack the lead casing or stuffing gland. The shafts on all the pumps were worn out in two months and were replaced with bronze. The wear on the bronze shafts is undetermined. The repairs on the pumps will not be a serious matter, since new casings, runners, and shafts are easily made. Low-pressure air-lift pumps offer more advantages, on account of freedom from moving parts in the corrosive solutions, and are recommended.

The pure rubber acid-proof hose used for the transfer of solutions showed no deterioration at the end of two months. While the initial cost is high, it is the only hose that will resist the corrosive solutions, and it is indispensable for handling solutions from the pumps on top of the vats. Lead-lined iron pipe is recommended for the rigid pipe connections, and wooden, lead-lined, or concrete launders provide the simplest means for the transfer of solutions from one leaching vat to another.

The tailing will have to be removed from the vats by machinery. No portion will run out by gravity unless it contains a high percentage of water. Since the tailing will be discharged containing small amounts of free acid and copper sulphate, the kind of metal used for discs, plows, or buckets in the excavating machinery was given consideration, although it is improbable that the quantity of acid or copper sulphate in the tailing will be sufficient to prohibit the use of cast iron, steel, or perhaps a high-silicon iron which has high acid-resisting properties.

Tests of Metals

Krupp bronze and 'Monel' metal were both submitted to the following tests. Pieces of each metal were allowed to stand in acid solutions and in acidified copper sulphate solutions of varying strengths, the bronze for two and one-half and the Monel metal for three months. The bronze precipitated the copper completely from all but the two strongest solutions. The Monel metal precipitated no copper, but passed into solution to a greater extent than the bronze. The results were as follows:

With Sulphuric Acid

Strength of acid, per cent H_2SO_4.	Loss in weight: Bronze, %.	Monel metal, %.
0.12	3.22	3.89
0.25	3.26	5.92
0.50	3.77	8.86
3.54	0.50	7.62
1.00	3.64	7.55
1.50	4.55	10.07

With Acidified Copper Sulphate Solution

Strength of solution, per cent Cu.	Loss in weight: Bronze, %.	Monel metal, %.
0.05	1.22	14.50
0.10	1.22	7.20
0.20	0.76	4.73
0.30	0.82	5.08
0.40	0.10	2.17
0.50	0.22	7.87

The Monel metal was also allowed to stand about six weeks in the following solutions:

	Loss in weight, %.
10% sulphuric acid	2.81
10% sulphuric acid and 10% copper sulphate (2.5% Cu)	4.88
10% copper sulphate (2.5% Cu)	1.99

A high-silicon iron, under the trade name of 'Duriron' was tested in a similar manner by these solutions. So far as could be observed at the end of a few weeks, this metal was not corroded in the least, but the experimental work was closed before this test was finished. The acid-resisting qualities of this alloy is well known, but it has the disadvantage of being very hard and brittle.

There have been almost as many methods proposed for precipitation of copper from solution as there have for leaching it from the ore, and today there is probably more uncertainty and more difference of opinion concerning the methods of precipitation than there is concerning the methods of leaching. Of all the methods proposed, only one has been demonstrated a commercial success, and that is precipitation on metallic iron. Lime or limestone was used in some of the earlier methods of hydro-metallurgy, but this yielded a precipitate that was little better than the ore itself. Sulphurous acid came into prominence a few years ago, but it involved difficulties of manipulation that have not been overcome, even in small-scale operations. Hydrogen sulphide, produced from iron matte, has been tried, but has not been developed on a large scale, and is likely to prove a troublesome reagent under such conditions.

Electrolytic precipitation is always attractive and has probably received more attention and intelligent experiment from skilled metallurgists than any other method. While some small plants use this method from time to time, it cannot, as yet, be called a commercial success. When working on a metallurgical problem, where the margin is narrow, one must always consider the materials at hand as the cheapest obtainable and most likely to permit profitable operations. As possible precipitants for the copper, I considered the following in the order named: natural sulphides of iron, artificial sulphides of iron, sponge iron, pig iron, and electric current.

Natural Sulphides of Iron

If acid leaching is used for the oxidized ore some other process will have to be used for the sulphide ore. It is probable that this would be some form of mechanical concentration. Tests had already been made by the ordinary methods of wet concentration at the University of Arizona before my arrival. These, by very careful manipulation, gave a recovery of 68% of the copper, 77% of the gold, and 63% of the silver, but the concentrate carried only 10.2% copper from an ore that assayed 2.3% copper, 0.02 oz. gold, and 0.22 oz. silver per ton. By a combination of flotation and concentration I was able to raise the recovery to over 76% and the grade of the concentrate to nearly 14% copper, although the flotation concentrate assayed nearly 24% copper. As is often the case when chalcopyrite has its source in igneous rocks, it is intimately associated with magnetite. Even fine crushing to 40 mesh failed to separate the magnetite from the chalcopyrite in this ore, and this destroyed the properties of the latter for flotation methods to a great extent, as well as lowered the grade of concentrate. However, by treating the concentrate on a magnetic separator, I was able to raise the grade to 18.5% copper. The magnetite itself carried nothing of value.

This, then, was the product and probably the best that can be obtained from the sulphide ores by the usual methods of treatment. It must be shipped to the Company's smelter at Douglas for treatment, or it must be smelted into matte and blister copper on the ground. If shipped to the smelter, it would certainly be advisable to raise its grade, if possible, either with or without removing the magnetite. Its efficiency as a precipitant was important but not essential, since any precipitation of the copper from solution and consequent enrichment of the concentrate would be a distinct gain. The only factor to make it a commercial success was the speed of the reaction, and in this it failed. However, having secured sufficiently speedy reactions from other natural sulphides of iron on previous occasions, I am not prepared to say the last word has been spoken in this case.

Artificial Sulphides of Iron

Two sources of this precipitant would be available. First, the matte produced by smelting the concentrate at the mine, and second, the matte that could be produced by smelting the low-grade pyrite at Bisbee. If soluble sulphides precipitate cupric sulphide from copper solutions and natural sulphides of iron precipitate cuprous sulphide, it is reasonable to expect the artificial sulphide of iron to do the same. Earlier experiments had shown me that iron sulphide precipitates metallic copper and not sulphide of copper from solution. This investigation was carried further and I found the reaction to be, not a simple transposition of the metals, but the following:

$$4FeS + CuSO_4 = Cu + FeSO_4 + Fe_3S_4$$

I found also that the precipitation of copper stops at this point, although free sulphuric acid will readily decompose the FeS_4 with the liberation of hydrogen sulphide. Therefore, less than 25% of the iron in pure iron sulphide is available for the precipitation of copper and the resulting product cannot carry more than 17.7% copper.

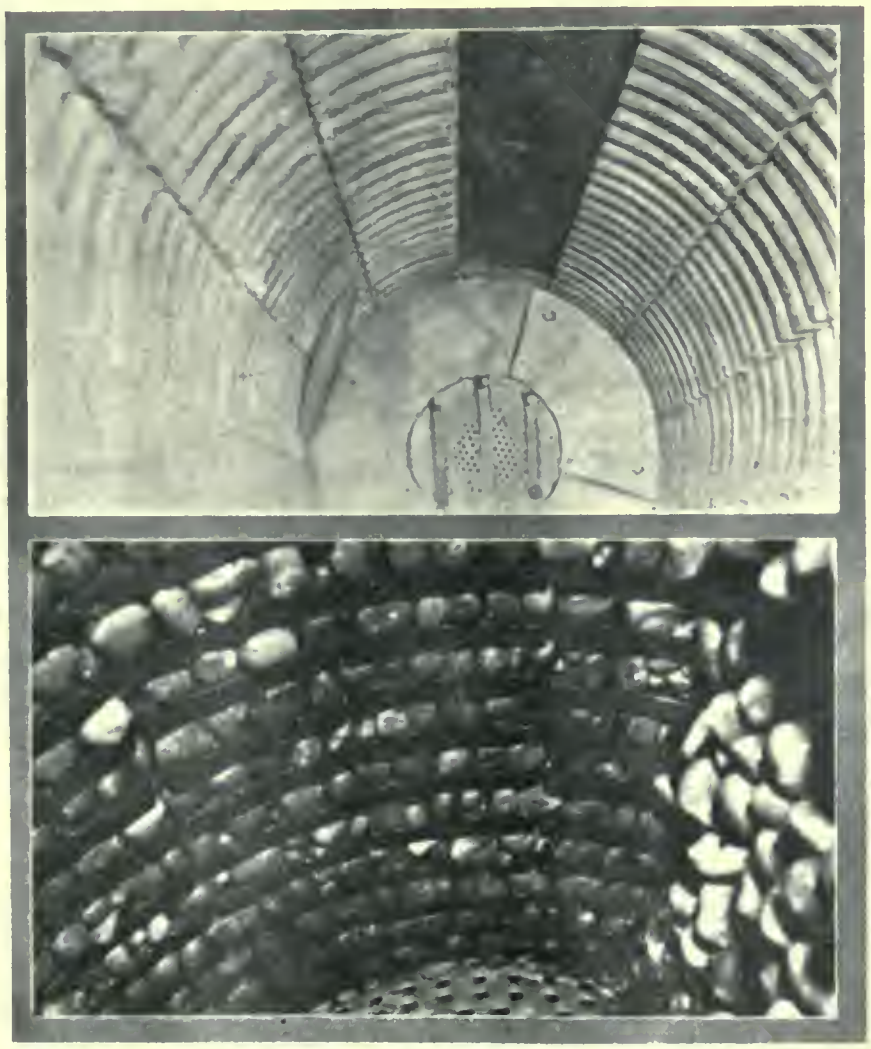
Increase in the copper content of a matte decreases its precipitating power so much that a matte containing over 30% copper precipitates practically no copper from solution. Nevertheless, the iron from the matte passes into solution to an appreciable extent. The only explanation I can offer for this phenomenon is a reduction of the cupric sulphate to cuprous sulphate and an oxidation of the cuprous sulphide of the matte to cupric sulphide, but I am not prepared to say that this is correct.

(To be continued.)

New Tube-Mill Liner

By J. G. MUELLER

A large number of different tube-mill liners are used in grinding gold and silver ores, each with its advantages and superiority over some other. A patent has been recently issued in the United States and Canada covering a tube-mill lining thought to be devised on entirely new and novel but practical lines. It was evolved



GLOBE AND MUELLER TUBE-MILL LINER

at Cobalt, Ontario, by Messrs. Globe and Mueller after continued trouble and excessive expense on account of the use of the parallel ribbed type of liner usually supplied by manufacturers of tube-mills. These could not stand the severe abrasion to which the coarse-grinding mills of the district were subjected.

From the halftones the construction should be readily understood; the narrow chilled iron ribs are placed circumferential to the shell of the tube, thereby forming a series of tapered and dovetailed pebble pockets alternately disposed between the ribs on a soft cast iron base of the usual form. The pocket or channel is widest in the direction of rotation of the mill, and the ribs taper inwardly toward the base, forming a tapered groove so disposed in relation to the direction of the rotation that the pebbles are automatically and quickly picked up and jammed securely into the grooves. This action takes place quickly and thoroughly.

It is absolutely essential that the initial load be a good mixture of all sizes of pebbles from marbles to number fours. The smallest pebbles find a secure hold in the crevices and voids of the larger ones, and the resulting surface, after two weeks, looks neat and is efficient: its roughness and irregularity tends to a better mixing and cascading action, and therefore better results in grinding.

So far there have been a dozen or more mills in Cobalt and Porcupine equipped with the liner, some coarse grinding, others on slimings, and in all cases they were installed after having been tried out against the parallel ribbed liner half and half in the same tube, or they have been recommended by operators who were satisfied with the results, showing a longer life.

It should be remembered that in coarse-grinding machines the liners are deprived of that cushioning and retarding effect in slimings mills, on account of the more rapid water circulation, which causes a more rapid discharge of much coarse particles. In other words, the voids in the pebbles of a slimings mill are filled with a thicker and more sluggish mass than in a coarse-grinding mill, therefore the abrasive action on the liners and pebbles of such machines is not so severe.

The cost of re-lining a 5 by 20-ft. tube-mill, with a full set of 72 pieces, including 2 doors, is as follows: 15,550 lb. at $3.75 per 100 lb., $583; a set of 130 bolts for same at 15c. per pound, $19.50; felt washers at 1c. each, $1.50; one mechanic, 12 hours at $3.50, $5.25; two helpers inside the mill, 16 hours at $2.50, $10; two helpers outside the mill, 16 hours at $2.50, $10; one man putting on nuts and washers, 16 hours at $2.50, $5; one-half of the mill foreman's time, $2.25; making a total of $636. The actual time, including the removal of the old liners, with six men up to time of refilling with pebbles, was 12 hours, and no difficulties were encountered.

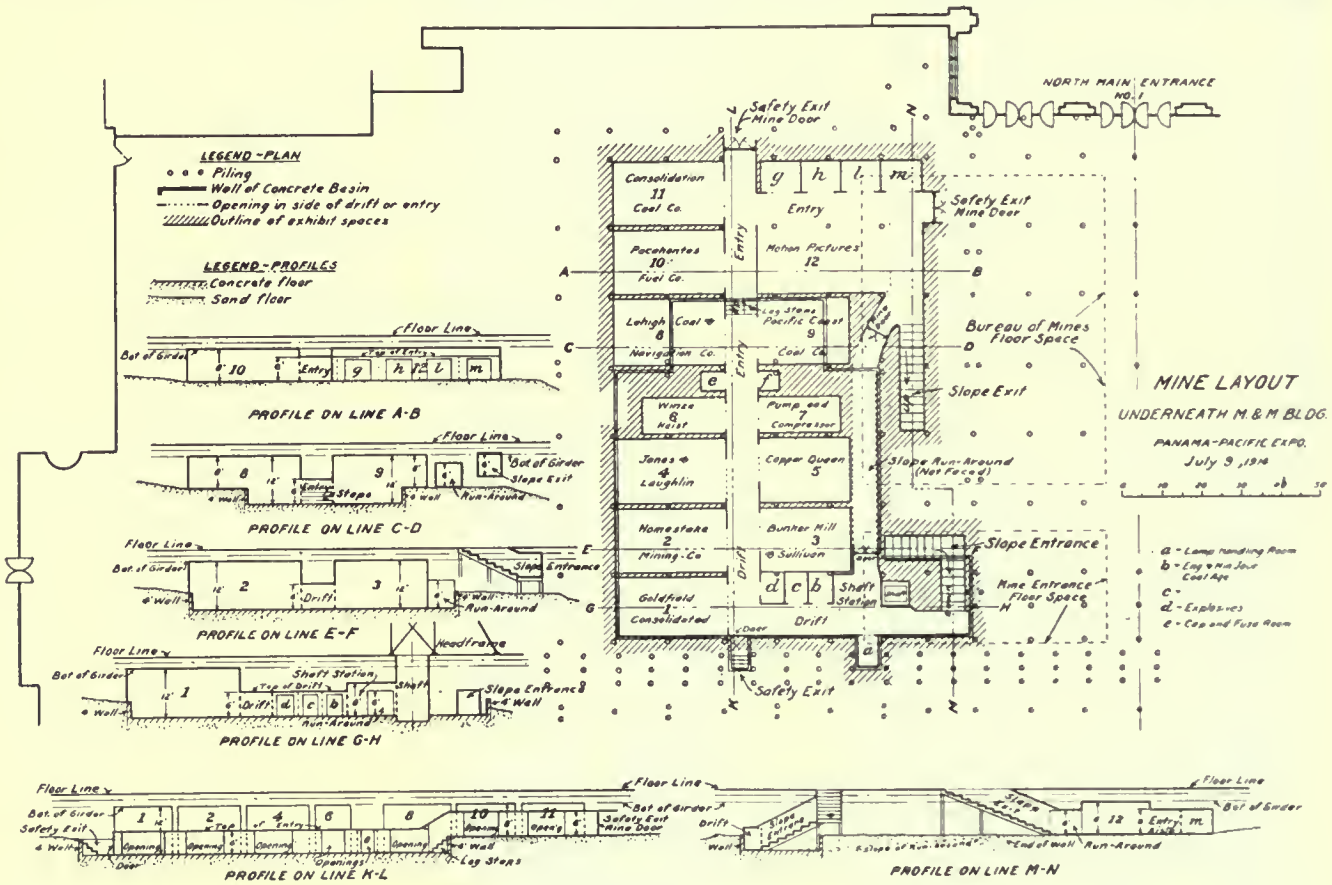
GOLD PRODUCED by Indian mines in May was as follows: Balaghat, £5445; Champion Reef, £44,131; Mysore, £76,371; North Anantapur, £4109; Nundydroog, £25,194; and Ooregum, £28,900.

Exhibition Mine at the Panama-Pacific Exposition

The plans for the mine beneath the floor of the Palace of Mines and Metallurgy at the Panama-Pacific Exposition, San Francisco, have now progressed under the direction of the Bureau of Mines to the point where it is expected that the most comprehensive exhibit of mines and mining subjects, including mining equipment and supplies, which has ever been prepared for the education of the general public, will be presented.

Characteristic working places, or stopes, will be prepared in the mine to simulate the character of the ore, or coal; and the methods of working, typical of some of the largest and most important copper, silver, lead, gold, and anthracite and bituminous coal mines of the country, and motion pictures will be shown in one of the rooms of the mine, illustrative of workings such as open-cut copper and iron mines and stone quarries, which cannot otherwise be shown in such an exhibit.

The plan of the mine here shown gives a good idea of the manner in which the exhibit is to be presented. The entrance to the mine may be made by a shaft or by a slope which has been placed adjacent to the Bureau of Mines space in the Government Exhibit. From the bottom of the shaft, which is on a lower level, the entry way leads past small rooms which will be used for exhibits of lamps, mining journals, etc., through metal-mining stopes, showing two levels in which various mining machines will be shown as working exhibits. Beyond the metal mining rooms the entry leads past a room typical of the Pennsylvania anthracite mines and a room typical of the Pacific Coast coal mines, in which the sloping veins occur. At this point steps in the entry lead to an upper level, along which are arranged rooms of bituminous coal mines. Opposite these, there occurs the motion-picture room, in which will be shown the operations of some of the great open workings of the country, by means of which iron, copper, gold, and stone are obtained. The exit from the motion-picture room leads direct to the slope exit from the mine which opens into the radium booth of the Bureau of Mines exhibit.



Here actual radium emanations will be shown while the visitors' eyes are still accustomed to the darkness.

The mine will be equipped with the usual tracks, trolleys, locomotives, cars, cages, hoists, motors, pumps, air-compressor drills, mining machines, signs, mine doors, etc., all of which will be installed as working exhibits. Each day there will be a demonstration of rescue and first-aid following an imaginary explosion in the mine. Rescue crews from the Bureau of Mines exhibit will enter the mine wearing apparatus and bring out the supposed victims, who will be given first-aid treatment in the surface emergency hospital, which will be one of the features of the Bureau's exhibit.

The exhibit should serve a good purpose in educating the public regarding the magnitude of the mining industry, the cost of its operation, and the amount of capital invested in its conduct.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

What is the Matter With Prospecting?

The Editor:

Sir—I read with great interest 'Operator's' article on prospecting, published in the *Mining and Scientific Press* of July 18. I have also read some dozens of articles on the same subject in various mining magazines during the past few months, and not one but was interesting and instructive, and well worth the space occupied.

I take it that every normal, intelligent man is interested in prospecting, using the word in the broad sense to include the search for, sale of, incomplete development, and general opening up of new mineral wealth. To discuss every phase of this subject in one article is impossible. I believe nearly every one will agree that a majority of the most easily found placers and lode deposits have been brought to light, and that most of those so far found have been developed, at least in part. Every great discovery, like Cripple Creek and Goldfield, leaves just one less such to be discovered. But discoveries of profitable orebodies will be made, and new mining camps will be developed within the present limits of the United States a thousand years from the present time.

In spite of the ranting of politicians, demagogues, and alarmists in general, supply and demand are the great controlling factors in economies. When there is a sufficient demand for an article, there will presently be a supply of that article. Some four hundred years ago, owing to the awakening from the Dark Ages and the consequent increase in business and commerce, there arose a great demand for gold and silver, as well as other metals. The demand was met. Again, owing to the great changes brought about throughout the better part of the earth by inventions, advance in general intelligence and living conditions, increase in the number and scope of industrial enterprises, commerce, etc., there arose a demand for a greater supply of gold, silver, and other metals in the fifties, sixties, and seventies of the last century. The demand was met. In the latter part of the last century, the world made stupendous strides in the arts of peace, and it began to look as if the supply of gold, as well as some other metals, was going to fall far short of the demand, but again the world's production of gold quickly quadrupled, in spite of the predictions of the wise ones to the contrary. Only a very few years ago, when the new and increased use of copper, coal, oil, and iron began to tax to some extent the productiveness of the best known supplies, a coal and oil shortage, and an iron and copper shortage, was confidently predicted in the not remote future, especially as regards copper. Not much of that sort of prophesying is heard at present. But if copper should go to 30c. per pound within two years, and the price of coal, oil, and iron double within a like period, then the wise ones would bray from every hilltop that these commodities would be entirely exhausted within a very few years, and then woe be unto us. As a matter of fact, if copper, or any other metal, should double in price within two years, and remain at that figure for any reasonable length of time, production would be so stimulated that within a few short years it would be selling even cheaper than at present.

It is hardly worth while to elaborate further on this point. The same general laws and facts will hold a million years from now. Those who agree with me will say amen at once, and those who disagree with me could not be convinced by my writing many volumes upon the subject.

If the present civilization should reach its zenith within 300 or 400 years, and then fall into decay and go back to the dark ages, there would be little demand for the metals and little would be produced, and that little would be much harder to produce at that time than ten or a hundred times the same amount at present. If then an awakening should come, and a few hundred or thousand years of cumulative progress ensue, every demand for metals would be met, although it called for ten times the present world's production of every one of them, including oil and coal. Just as soon as the shortage of any metal becomes acute enough, the supply of that metal will gradually increase until there is a sufficient supply for all reasonable purposes. This talk about the world's progress, intelligence, inventive genius, and productiveness having about reached its zenith is the merest rot, and proclaims the advocates of such foolishness as too conceited to be entitled to any consideration whatever. Merely because we have made great strides, or think we have (perhaps our posterity won't think so) in invention, general intelligence, education, sociology, hygiene, economics, increase of wealth, mining, agriculture, transportation, etc., during the last one hundred years, is absolutely no reason why we have about reached the limit. On the contrary, it is the best of reasons why we have only begun to make a start, and great progress is to be expected.

There is really nothing of consequence the matter with prospecting. Just to keep peace in the family, I

might admit that it may be slightly indisposed just at present, but certainly there are no alarming symptoms, and to send for the doctor would be very foolish, indeed.

Admitting for the present that there is at least a slight indisposition, what is the cause and cure? The cause is the same as in most cases of indisposition—indigestion. There are more prospects than there is capital available for their development. There are thousands of incorporated mining companies that never shipped a carload of ore, and yet are good prospects. If all the mining companies in the United States could sell all of their stock at par within 30 days, it would require all the money in existence available for investment purposes. No other enterprise could raise a dollar for any purpose for years. This does not take into account thousands of prospects that have never been incorporated, and most of them are of at least some merit.

There is a constant demand for money to finance railroads, public-service corporations, agriculture, industrials, mining, governments, states, municipalities, etc. Of course, there are fashions or crazes in investments. At certain periods railroad stocks and bonds seem to be all the craze with investors. At another time public-service corporation investments are very popular and no one seems to want to put money into steam railroad securities. Just now railroad securities are somewhat in disfavor. At other times, the investing public wants real estate, and all kinds of real estate booms in consequence. At another time, municipal bonds are very much in favor, as, for instance, right now. Then again, at another time industrials are very popular, as for example from 1898 to 1905, or thereabouts. Once in a generation or so the public gets the mining fever, and must needs buy mining stock by the pound, hundredweight, ton, and carload. Then is the time the prospector and his best friends (or should I say his worst enemies?), the wild-catter and promoter, wade in clover up to their ears.

For several years mining securities have not been in very particular favor, for much the same reason that railroad securities are not much in favor just now. Owing to such men as Charles S. Mellen in the railroad world, and Charles E. Brown, of Boston and Chicago, in the mining world, people have been duped, or think they have. Then, too, the supply of railroads, on the whole, somewhat exceeds the demand just at present. For this and other reasons they are not earning a sufficient rate of interest on the money invested. In like manner, the price of metals, mines, mining stock, mine prospects, etc., just now show that the supply, as a whole, somewhat exceeds the demand.

'Prospector' wants at least $5000 to $25,000 for his 'mountain of ore,' said 'mountain of ore' being exposed at one or two places, and 'Operator' is willing to pay but $1000 to $10,000 at most. 'Operator' says it looks as though 'Prospector' would die of starvation in sight of food. 'Prospector' says he would rather die of starvation at once and be done with the agony than to try to eke out a miserable existence on the few crumbs that 'Operator' offers him. If 'Prospector' incorporates his prospect with 1,000,000 shares, par value 10c. per share, which he considers exceedingly conservative, he can possibly—if he is a good 'rustler'—sell five thousand, or ten thousand at the outside. This gives him $500 or $1000, which does not go very far toward making a mine of a prospect. Why, if he has a good prospect, can't he sell more than $500 or $1000 worth of stock? Because the supply of such wares exceeds the demand. The public is afflicted with a slight case of indigestion from trying to assimilate too much mining stock and too many mine prospects, and many other kinds of stocks and prospects.

I might add as minor and contributory reasons for the supposed lack of interest in prospecting: (1) The constant 'knocking' by all the leading Eastern magazines for the past seven years of any kind of mining securities or mining properties; (2) the millions lost in mining ventures and mining stocks between 1902 and 1907; (3) the total ignorance of real mining by 95% of the public; (4) the laziness or lack of judgment of the prospector, in not better opening up his prospect himself than he generally does before offering it for sale to some capitalist, or trying to sell stock; (5) the inability of the prospector and operator to see things alike, or anywhere near alike; (6) the continual 'knocking' of prospecting by those well meaning people who must have it that the patient is sick unto death; (7) the inability of the prospector to get most millionaire mining men, who were once poor prospectors themselves, even to listen to a story about a likely prospect, much less to put up a cent on any term for its development; (8) the absolute lack of any interest whatever on the part of the big mining companies in small undeveloped prospects; (9) the lack of any recent great discoveries, like Goldfield and Cripple Creek, which appeal mightily to the public; (10) the absorbing of so much money lately by the automobiles, moving pictures, and many other fads, fancies, speculations, and extravagances; (11) the tendency most mining engineers have to reject every prospect in order to be on the safe side, and because it does not look enough like a mine—no prospect looks like a mine until it is developed into a mine, when, of course, it looks like what it is, a mine; (12) the 'knocking' of every prospector's property by every other porspector; (13) the nation-wide crusade against gambling and speculating that has to some extent killed the gambling spirit in the American public—a very good thing, too, it ought to be further discouraged; (14) the lack of any general moral support and encouragement of the prospector and his business just now (a few mining magazines and Western newspapers, it is true, are trying in a half-hearted way to encourage the prospector); (15) certain alleged imperfections in our mining laws, and alleged rulings and practices of those who administer the forest reserves; (16) psychological

hard times; (17) wars and rumors of wars. But the general reason that includes all the rest, is, as pointed out above, the lack of any great public interest in mining. The reason there is no great public interest in mining is, as also pointed out above, that the demand for the miner's commodities—prospects, mining stocks, metals, etc.—is hardly equal to the supply. If for any reason there should suddenly come such a demand for gold, lead, zinc, copper, coal, oil, and iron that the price of each would double within five years and remain so for any considerable length of time, then there would be a mining boom such as the world never yet saw. There would be a regular mining craze, a perfect debauch, and the prospector, for a while, would bathe in champagne, ride in $10,000 limousines, and build palaces galore. And as for the wild-catter—those that have starved to death during the past seven years would turn over in their graves, and those in jail would speedily procure a pardon, or break jail, and become exceedingly active; and those who are now eking out a miserable existence by doing odd jobs, would suddenly become prosperous and flourish like the proverbial green bay tree.

In conclusion, I wish to say again that there is nothing seriously the matter with prospecting. There is a little dullness in the business for the reasons pointed out. There is no tremendous boom in prospecting just now, of course, and there won't be until, for some such reasons as I have mentioned, the general public becomes greatly interested in the prospector and his prospects, and in mining in general. But I will venture to say that there are even now hundreds of men of more than ordinary intelligence out in the hills in their automobiles (some with their families), scouring the hills for new orebodies, and examining old discoveries. We must not forget that the business of prospecting is undergoing a transition from the old lone, long-haired man, with one or two disreputable burros, frying pan, coffee pot, grubstake, and old fashioned pick and shovel, exiling himself in the hills for months at a time, to the up-to-date, modern prospector with his automobile and assaying outfit. As to which is capable of producing the better results, the old-time prospector or the strictly modern prospector, I am not yet prepared to say.

Park City, Utah, July 21. CHAS. MOORE.

[With this excellent summary of the situation direct from the field, we must close the discussion of prospecting for the present. Interesting as the subject is, and helpful as we hope the discussion has been, we must reserve our space for other topics in turn. We are grateful to the many whose letters we have published and to the others for whose comment we have been unable to find room, and we trust that some of our friends may soon locate another Goldfield, if indeed it has not already been staked. There is no competition in gold mining, and the finder of a new high-grade district will help his fellow-prospectors quite as much as himself.—EDITOR.]

Revision of Mining Laws

The Editor:

Sir—Regarding the discussion on revision of mining laws, in issue of July 18, by F. R. Ingalsbe and C. K. Colvin, the present requirements necessary to patent mining property vary with every change in the administration of the Land Office at Washington; the law should be clear, distinct, fixed, and not left to the whims of any man or set of men, giving Pinchotism an opportunity to ruin the mining business.

I believe that it is hard to improve upon the Mexican mining law. Anyone can locate all the mineral land he desires, within 90 days; thereafter it must have been surveyed, examined, and reported upon, and monuments of rock and mortar or cement, about 2 ft. square and same high, erected upon the external boundaries, in such a position that, from each, the one in front and one in back can be seen, plainly. No location is valid when overlapping another claim. After patent is obtained, a tax upon each claim and fraction thereof is required, which is payable every four months. If not paid in the month due, the next month the penalty tax is 50%, the second month 100%, and the third, one loses the property. Notice is then posted upon the bulletin of the mining agent's office, and he notifies the general office in Mexico City. Within six or eight weeks the general office notifies the agent of the district where the claim is located, and the agent posts a notice for 30 days that the claim is again open to re-location, to anyone except previous locator. The engineer in charge of location work must be a registered engineer of Mexico, if there is one resident in the district, or else an engineer agreed upon by the locator and the mining agent of the district. The name of the claim must be painted distinctly on each monument.

No work whatever is required, and title is perfect as long as taxes are paid. After the claims are surveyed and reported upon, the mining agent posts a description of the claim for four months, and causes to be published in the official paper of the state (only one) a description of same, for 60 days. During four months anyone may protest the claim if cause is shown.

If discovery of mineral is demanded, it should be anywhere on the claim, allowing one or more non-mineral discovery claims, owing to their size. If one is willing to pay say $3 per acre for mineral land, generally not worth 25c. for other purposes, and pay taxes on this, why not let him locate all that he wants? It is known that the $100 per claim annual assessment work, nine times out of ten, is a farce. I recently examined an old camp where a few men are holding the whole district, and, with one or two exceptions, practically no work is being done. On most of these claims the only way one could determine where they were or make other valid locations in their vicinity, would be by procuring a copy of the location certificate and put a competent surveyor in the field.

Ely, Nevada, July 23. G. L. SHELDON.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

In draining Kerr lake at Cobalt, Ontario, the pumps removed 325,000,000 gal. of mud and water at an average of 6000 gal. per minute for 38 actual working days.

Four small graphite-coated diamonds have been found in the Premier mine, Transvaal, and is an addition to the already large list of unsolved problems connected with diamonds.

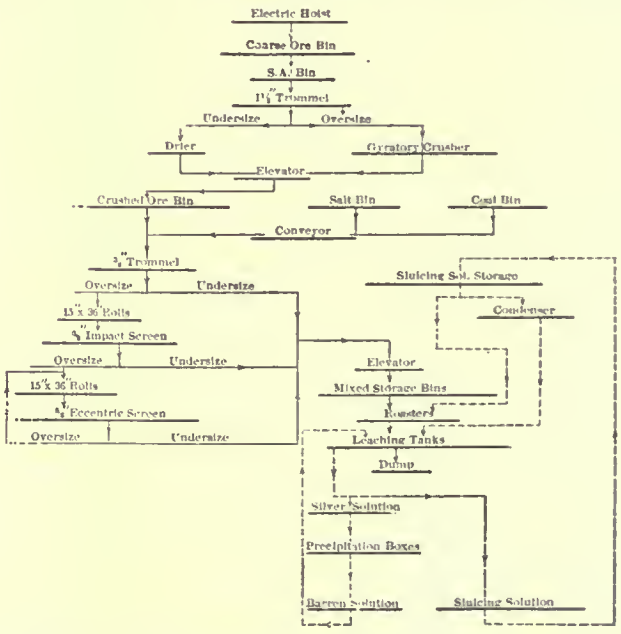
Bullion-melting furnaces using coke should be provided with a seamless cast iron ashpit. In case of breakage of a crucible during melting bullion, it is then a fairly easy matter to recover everything which may have been spilled. An ashpit constructed of brick is very hard to clean, and concrete is not much better. The time, trouble, and satisfaction of knowing that all the bullion has been recovered, well repays for installing an iron ashpit.

Electric power generated at the Waihi Grand Junction mine, New Zealand, in 1913, from four 600-hp. Babcock & Wilcox boilers, three 580-hp. Parsons turbines, and one A. E. G. turbine of 2680 hp., totaled 6,588,708 units at a cost of 0.9376c. per unit, or $81.90 per kilowatt per year. The maximum load was 1742 hp. This included two Ingersoll-Rand air-compressors, 26 motors in the mill, 15 motors in the mine, 14 motors in the power-house, and 6 motors for sundry purposes, with a total of 2487 horse-power.

Dynamite and Trojan powder amounting to 435,525 and 15,394 lb. respectively, exploded in the Panama canal magazine at Mindi on July 5. A large hole was made in the ground where the magazine stood, a huge mound of earth formed, and the Mindi river was filled 10 or 12 ft., making it take a new course. The magazine was so constructed and surrounded by hills that any explosion would not affect the villages of Cristobal, Colon, Mount Hope, and Gatun. It was 9 by 48 by 112 ft. in area and was large enough for 600,000 lb. of dynamite. The detonator house, 10 by 17¼ by 33 ft., and 150 ft. away, was partly damaged, but its contents did not explode. The cause of the explosion is attributed to spontaneous combustion, although the place was inspected every day.

Water used by the partners of the Kalgoorlie and Boulder Mines Water Trust, Western Australia, which is a concern connected with the Chamber of Mines, represents the large properties at Kalgoorlie, and deals with the water bought from the Government of that state, was as follows during the half-year ended March 30, 1914: sluicing services (disposal of residue) at 36c. per 1000 gal., 31,910,000 gal.; sluicing at 84c. per 1000 gal., 9,022,000 gal.; and general services at $1.68 per 1000 gal., 166,286,300 gallons. This was a decrease of 15,551,200 gal. compared with the same period of the last year, but an increase of 7,336,000 gal. over the year ended September 30, 1913. About 850,000 tons of ore was treated during the term reviewed, the production of 11 mines. To supplement the great 353-mile water scheme supplying this and other mining and agricultural districts, a 10,000,000-gal. reserve tank has recently been constructed at Kalgoorlie. In the event of a break or necessary repairs, the reservoirs there have about a week's supply.

Chloridizing leaching at the Mines Operating Co.'s plant at Park City, Utah, is described in the July *Bulletin* of the A. I. M. E. Ore treated contains 6 to 14 oz. silver, 0.01 to 0.015 oz. gold, and 1 to 2 lb. of copper



Flow-sheet of Mines Operating Co.'s mill at Park City, Utah.

per ton, with a little lead and zinc. After roasting the ore is leached by a solution made up of soluble salts, mostly NaCl, from the roasted product, carrying in addition about 4 lb. of free sulphuric acid. Leaching costs from 17 to 44c. per ton. Recovery of metals is done by passing the leaching solution through boxes filled with any kind of scrap iron, and the precipitate of gold, 1.78 oz.; silver, 6868.5 oz.; lead, 13.2%; copper, 36.94%; iron, 2.5%; sulphur, 1.6%; and zinc, *nil*, is shipped for refining. The mill treats 160 tons per day with a good extraction and reasonable cost.

MINING IN THE FAR NORTH*

Valdez and Prince William Sound

By E. E. HURJA

Prince William sound was discovered in 1778 by Captain James Cook It was visited by other explorers later, Vancouver, in 1794, contributing maps of the district. Although Russians had trading posts at different points along the sound, but little prospecting was done. Reports are that copper prospecting was carried on by the Russians in the mountains of western Hinchinbrook island. The first activity of Americans in the copper fields was noted in 1897, when the staking of the Gladhough claim on the east side of Virgin bay started the excitement. This claim was the nucleus of the Ellamar mine. The Bonanza property, on Latouche island, was staked the same year and has been a good producer.

The Bonanza has shipped regularly since 1904. The mining is largely done from an open hill face, and the ore trammed through two tunnels to the quarry floor. Considerable driving has been done, as well as prospecting with a diamond-drill.

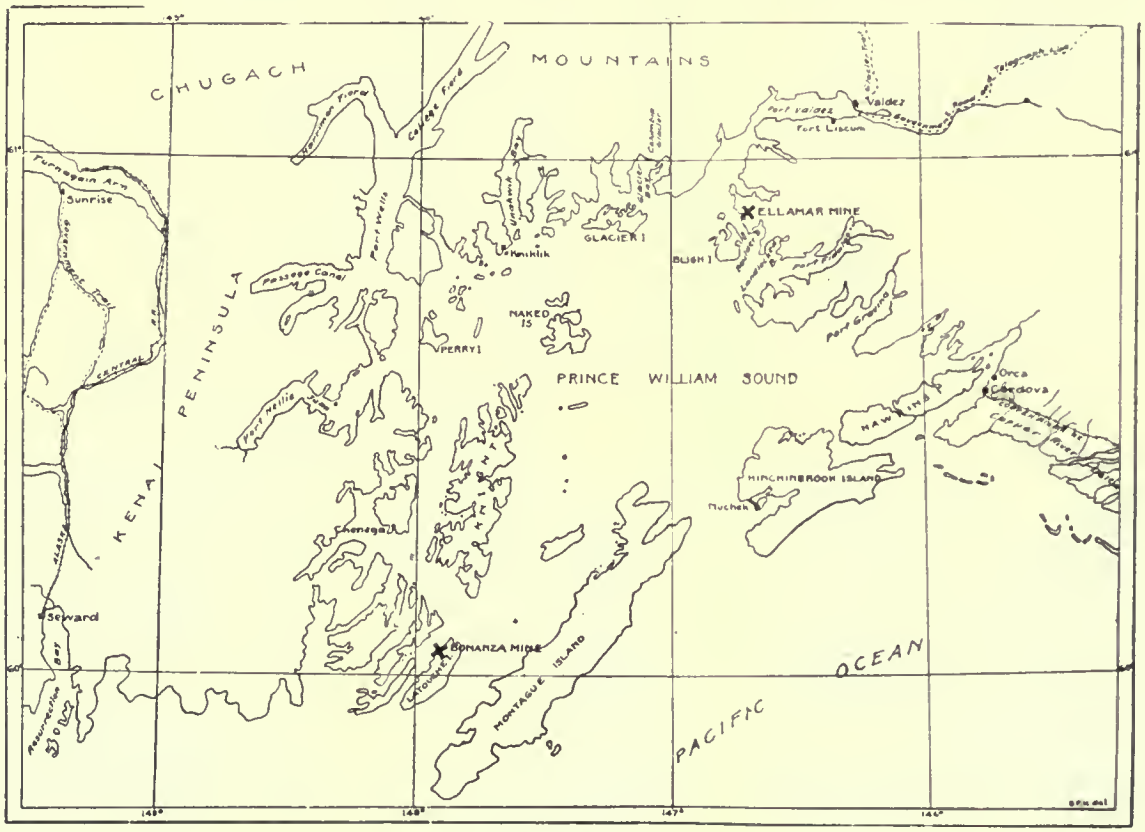
The Ellamar Mining Company's claims, operated by L. L Middelkamp, are situated on Virgin bay, 28 miles from Valdez. The Gladhough claim, located by W. L. Johnson in 1897, is the centre of development. A 600-ft. shaft, with levels at intervals of 100 ft., taps the orebody, a lenticular mass carrying copper, gold, and silver. For the last two years a start has been made toward cleaning out the remnants of the orebody. Work is now conducted between the 300 and 400-ft. levels. The fill system of mining is followed with slate waste used as filling material. A 1200-ft. Nordberg compressor supplies power to the drills, including one diamond-drill. The drill has found new orebodies, but the extent has not been definitely determined as yet. A 10 by 12 Duplex double-drum hoist is used, and will be supplemented by another to be erected this fall. A new Broderick & Bascom tram, with a capacity of 200 tons per hour, has been built and was to be ready for use before August, according to the manager, Middelkamp. The tram will connect the bunk-

[*Previous articles in this series by Mr. Hurja on mining in Alaska and the Yukon have been 'Mining Revival in the Ketchikan District, Alaska,' July 4; 'Wrangle, Alaska,' special correspondence, July 11; 'Developments of the Alaska Gold Mines Co.,' July 18; 'Juneau, Alaska,' special correspondence, July 25; 'Cordova, Alaska,' special correspondence, August 8. Mr. Hurja is now in the interior and in subsequent letters will give our readers full accounts of present conditions in each of the great producing districts of the Far North.—EDITOR.]

BIRD'S-EYE VIEW OF PRINCE WILLIAM SOUND DISTRICT.

ers at the mine with the dock bunkers, a distance of one-half mile. The mine will be able to ship 5000 tons per month with the completion of the new tramway. F. M. Jordan, of Seattle, and W. M. Rust, of Tacoma, are the chief owners of the property.

Engineers of the United States S., R. & M. Co., Messrs. Hughes and Anderson, are in the district now, conducting examinations of different properties. Sampling parties are in the field, making Valdez the headquarters. The Three Man Mining Co. claims at Landlock bay, which has shipped considerable ore, is one of the groups under examination by the new Company. The Fidalgo-Alaska Copper Co. claims, at Fidalgo bay, also are being examined by the engineers. No work has been done there since April. Two-hundred-ton bunkers at the mine are connected with the 1000-ton bunkers at the dock by an aerial tramway 2600 ft. long. Two thousand feet of underground development work has been done.



MAP OF PRINCE WILLIAM SOUND.

The Rua and Valentine properties on Knight's island also are to be sampled by the United States Smelting engineers. Larson Brothers are doing assessment work on their holdings on Knight's island. The Viking group, five miles from the head of Fidalgo bay, is being developed in a small way.

The Fidalgo Mining company owns 24 claims at Fidalgo bay. The development is confined to the Winchester and Elgin claims, on which two adits have been driven, the lower one serving as a working adit. A surface tram 900 ft. long connects the portal with the upper terminal of the Riblet two-bucket aerial tram which carries the ore a distance of 2000 ft. to the main bunkers at the dock. Development work at the mine is to be centred on a 1200-ft. adit, which will start 200 ft. from the beach and tap a proposed winze from the present workings. A depth of 600 ft. will be attained. T. W. Blakney is in charge of the work at the mine.

Prince William Sound Mining Company

Nineteen claims, owned by the Prince William Sound Mining Co. on Copper mountain, are being surveyed for patent. Adit work aggregates 6000 ft. Discovery of copper at Unakwik bay in Port Wells has aroused interest in that district. The most recent find was made by Martin P. Anderson, who owns the Snowstorm group of claims. The claims have been bonded by F. S. Sinnicks, of Boston, for $50,000, who planned to have a prospecting party at work before August. A 5-ft. vein of ore carrying copper, galena, and silver has been traced for 3000 ft. on the claims. Seventy feet of adit has been driven by George Wagner and Harry Wilson on an 8-ft. vein of copper-bearing ore at Siwash bay.

The Work of the Granby Consolidated M., S. & P. Co., in the Valdez district, is the largest construction work in the Prince William Sound country at present. Over a hundred men are being worked, with a monthly payroll of from $10,000 to $15,000. E. E. Campbell is engineer in charge, with G. E. H. Smith superintending the construction. The 15 claims making up the Midas property have been taken over by the Granby interests, and work at the mine will start next week. A main working adit, 6 by 7 ft. in dimensions, which will tap the ore, will be connected with the present workings. Five-hundred-ton ore-bins at the mine will be connected with a 3000-ton bin at the beach by a Riblet aerial tram five and one-half miles in length. At the mine, a ten-drill Ingersoll-Rand compressor has been installed, and will be operated by electric power. A small machine-shop has also been constructed. The ore-bins at the beach will be at the low water mark and the dock 200 ft. farther out. A belt-conveyor 24 in. wide will carry the ore from the bunkers, at the rate of 200 tons per hour, to an elevation of 30 ft., there to be released into iron chutes. An electric motor will operate the conveyor. The Midas orebody is pyritic and contains copper, gold, and silver, occurring in a replacement shear zone in schist. Development work undertaken by the Alaska Syndicate, which operated the property up to two years ago, aggregates 2000 feet.

Though copper is still the mainstay of the district, the gold discoveries near Valdez are attracting considerable attention

and are producing some money. On July 6, $20,500 in bullion was shipped from Valdez, the result of 14 days' operation of the quartz mines. The output of the quartz mines this summer is estimated will be $300,000.

Port Valdez

Port Valdez, the main gold district, is an inlet trending northeastward from the main waters of Prince William sound. Gold was first found in the gravels at the mouth of Mineral creek in 1894, but the mining done at that time did not amount to much. Four years later, the work of the prospectors bore fruit and additional placer claims were staked on Solomon gulch, on the south side of the inlet and about opposite the glacial moraine on which the town of Valdez was built. The place was first known as Copper City and was the outfitting place for the thousands of prospectors who swarmed over Valdez glacier on their way into the interior to the Klondike and other discoveries. Quartz mining in the district is confined to small veins of rich ore. A number have been discovered and some have been worked profitably. The most successful mining venture of the district, the Cliff, gave stimulus to prospecting after 1909 and the district has forged ahead rapidly since that time.

Work has been suspended now at the Cliff mine and the affairs of the Cliff Mining Co. are rapidly being settled. A 4% dividend was declared July 6, and another, the final one, will be forthcoming soon. The Cliff Mining Co., owners of the lease on the Cliff claim, has produced $900,000 in gold and paid $231,000 in dividends, aside from royalties. The claim is situated eight miles from Valdez at the east entrance to Shoup's bay. Sea-water invaded the workings recently and so rapidly that one pump on the lower level was lost. Operations at the property in the future depend on the desires of the owner, who is in the States. The Sealey-Davis property, adjacent to the Cliff, is under lease and bond to J. Devinney. He is continuing the adits, which have attained an aggregate of 1600 ft. The Three in One claim also is being worked between Gold creek and Shoup's bay. An adit 200 ft. long is about to be started on the Tomboy property on Pickett bay. F. L. Wagner, who has a $40,000 bond on the claims, has leased the property to the Colln-Murray company which is engaged in active development. A 40-ft. adit has been run on the lode with a width of 3 ft. If the work from the new adit is satisfactory, plans for a reduction plant and tram will be made. Work on the larger of two shoots on the four claims comprising the holdings of the Gold Bluff Mining Co., adjacent to the Cliff property, will be started this fall. The claims are being surveyed for patent now. The adit work on the property aggregates 240 feet.

The Blue Bell Claim

The Blue Bell claim, situated on Valdez bay at the entrance to Shoup's bay, 1500 ft. from tidewater, is being developed from a cross-cut 120 ft. long, which taps the ore at a depth of 60 ft. The vein is from five to six feet wide and carries free gold. The claim is owned by F. M. Boyle and associates.

Operations on the Cameron-Johnson property, situated 17 miles from Valdez and five miles from Shoup's bay, are being continued. On July 10, work was started on the construction of a 3800-ft. Bleichert tram to replace the present temporary tram between the mine and the mill. The Company owns 23 quartz and three placer claims. The quartz operations are being centred on the Treasury Note, Walloper, Gold Certificate, and Mazuma claims. Adits, raises, and drifts on the Treasury Note aggregate 478 ft. in length, with a maximum depth attained on the orebody of 217 ft. Stoping operations are being conducted between the middle and upper levels, a raise is being driven to connect the lower with the middle level and both the middle and lower levels are being extended along the vein. Three shipments of ore from the vein made to the smelter yielded from $104 to $226 per ton. A 100-ton lot of selected ore milled on the property yielded 180 oz. gold. On the Gold Certificate claim, 68 ft. of adit has been driven; on the Walloper 35 ft. On the Mazuma, a 110-ft. cross-cut has been driven, with a 60-ft. raise to the surface. The claims are at an altitude of 3600 ft., with the mill equipment at an altitude of 2000 ft. The five-stamp Risdon mill on the property will be supplemented this year with a 7-ft. Lane mill and two Monarch concentrating tables, the equipment now being on the ground, ready for erection. The mill is operated by water-power derived from a Pelton water-wheel with a 246-ft. head. Sidney Drake, general manager, expected the new equipment to be in use and the mill operating to its full capacity by August 15. Forty men are being employed at the mine.

GOLD KING MINE, VALDEZ.

A contract for driving 100 ft. of adit on the claim of the Rambler Gold Mining Co., situated on Shoup's glacier above the Cameron-Johnson property, was let in July by F. L. Wagner. The new work will make the total on the claims 600 ft. A drainage adit to unwater the workings of George Herman and William Eaton at Bettles bay, Port Wells, is contemplated. The group comprises five claims, on which 115 ft. of shaft has been sunk with 130 ft. of driving on a vein varying in width from 20 to 24 in. Water put a stop to the work two weeks ago.

Ramsay-Rutherford Mill

Construction of the Ramsay-Rutherford mill is continuing steadily. The Ramsay-Rutherford company owns a group of ten claims situated near Valdez glacier 12 miles north of

Valdez at an elevation of 3500 ft. A 150-ft. double-compartment, vertical 9 by 6 shaft has been sunk. On the 50-ft. level, 135 ft. of drifts have been driven on the vein. On the 150-ft. level, the vein has been tapped, but no driving has been done as yet. On the 50-ft. level, a cross-vein 12 in. wide was found 80 ft. from the shaft. The main lode varies in width from 6 in to 11 ft., with an average width of from 20 to 24 in. Forty-six tons shipped to the Tacoma smelter in 1912 yielded average returns of $87 per ton. The foundation for a five-stamp Joshua Hendy mill is in and the mill building is under way. The mill will be in operation in September. Twenty men are employed. If work on the 150-ft. level justifies, a 600-ft. cross-cut to serve as the main working level, with the portal at the same altitude as the mill, will be started this fall.

The Golden Eagle Mining company, operating at Port Wells, is planning to erect a five-stamp mill this fall. Two hundred feet of adit has been driven on the vein. The mine will be connected with the mill by a 1000-ft. aerial tramway. Edwin Griset is the manager. M. J. Callaghan, who has a $50,000 bond on the property of William Hogan and Peter Black in Harriman's fiord, plans to continue the adit on the claim this fall. Present underground work on the vein totals 200 ft. The lode is from 4 to 16 in. wide. A lode from 1 to 6 ft. wide on the Sweepstakes claim at Harriman's fiord will be under development by the end of July, according to Mr. O'Neil, one of the owners. Two small shafts and 150 ft. of adit comprises the present development. The work on the Alice Mining company claims at the head of Shoup's bay is at a standstill, pending a settlement of financial difficulties. Two drifts totaling 270 ft. and a 300-ft. adit make up the development on the lode, which varies in width from 6 in. to 2 ft. long. Two hundred feet of work remains to be done on the 1000-ft. adit on the Ellis-Imperial group between Shoup's bay and Gold creek. Work will be started soon on a drift along the vein where it outcrops on the surface.

A test shipment of 3800 lb. crushed July 21 at the mill of the Mountain King Mining Co. yielded $100. The Company owns five claims eight miles from the mouth of Mineral creek at an altitude of 3000 ft. Two thousand feet of driving has been done on the property, with a maximum depth attained on the 20-in. vein of 235 ft. W. L. Smith, manager, let a contract the middle of July to haul 200 tons of high-grade ore from the mine to the mill. The mill is a two-stamp Hammond, with 1000-lb. stamps, situated at an altitude of 800 ft. A survey has been made for a 4300-ft. tramway to connect the mine with the mill.

A Straub mill is being erected on the Big Four property, owned by San Mateo, California, people. Work on the claims, which are at the head of Mineral creek, aggregates 300 ft. Development of the orebody is being continued. The Collins-Fish property, four miles from the head of Passage canal, has been bonded to B. F. Millard. Prospecting has been confined to the surface. A contract to run 90 ft. of adit on an 18-in. vein on the No. 9 property on Portage bay, one and one-half miles from Golden, has been let. One 60-ft. shaft and another 50 ft. deep have been sunk on the Ohme property, above No. 9. The vein varies in width from 10 to 30 in. Prospecting on the Hogan-Olson claims, two miles from that of the Granite Minting company, is being conducted by lessees working under a lease and bond of $70,000.

The Granite Gold Mining Co. of which J. E. Chilberg, Jafet Lindeberg, B. F. Millard, and Ray Millard are the owners, has a group of three claims near Hobo bay on Port Wells. The claims are 1000 ft. from tidewater, with an altitude of 600 ft. Development on the Center claim consists of a 156-ft. cross-cut tapping the vein at a depth of 106 ft. Driving on the vein aggregates 240 ft. A 152-ft. raise has been driven to the surface 106 ft. from the portal of the adit. A 50-ft. winze, with dimensions of 7 by 10, has been sunk, and driving started on the vein. This lower drift totals 250 ft. Ore from the lode, which varies in width from 2 to 13 ft., maximum width being attained in swellings, has averaged $38 per ton. Work was started in April 1913, and since March 20, ore to the value of $32,000 has been mined. The clean-up made July 3, yielded $10,500 for a 22-days' run of a 7-ft. Lane mill. Power at the mine and mill is derived from gasoline engines. A 25-hp. Foos engine operates the compressor and furnishes power for a No. 5 Cameron sinking pump. A 15-hp. Fairbanks-Morse gasoline hoist is used, and a Triplex station pump, operated by a 12-hp. engine, has just been installed. Sinking is being conducted from the second level. Thirty-five men are employed. From the portal of the adit, the ore is trammed over a 320-ft. trestle to bins, and carried from there by an aerial tramway 340 ft. long to the mill. Mill equipment consists of a Blake crusher, a 7-ft. Lane mill, and a Deister table, all operated by a 20-hp. West Coast engine. Additional equipment has been ordered, to consist of a set of Allis-Chalmers rolls, style B, which, operated in connection with the Lane mill, will double the capacity of the present reduction plant. A Wilfley concentrating table will be added. Tailing is impounded. One ton of concentrate worth $50 in gold is derived from 60 tons of ore. Mr. Millard says the milling equipment will be increased with a 10-stamp outfit if results on the next level justify. Freighting costs are not high, for goods are towed to the beach on barges from Valdez and then hauled on a corduroyed road to the mine. Fuel is distillate from the Katalla fields, delivered in drums at the mine for 14c. per gal. The vein has a northwest-southeast strike and dips northeast at an angle of 45°. One-half of the vein is in altered granite; grading from that into a slate formation.

Gold King Mining Company

An output of $15,000 per month is being maintained at the Gold King Mining Co. property, 15 miles from Valdez above Shoup's bay. The equipment comprises a Dodge crusher, a 3½-ft. Huntington mill, and a Risdon-Johnson concentrating table. Underground work on the orebody totals 1850 ft., and the maximum depth attained is 76 ft. The vein varies in width from 16 to 50 in. Another vein, averaging 8 inches in width, is being developed by adit. The mill operates but six months in the year and the summer payroll amounts to $2500 per month. The clean-up made July 4, gave $5800 for 10 days' run. In the summer of 1913, a 35 days' run yielded $18,500. A two-stamp Nissen mill will be installed this fall. Gasoline engines supply power to the mill equipment, consumption being at the rate of 30 gal. per 24 hr., with a cost per gallon of 55c. Difficulty in freighting the outfit to the mine was overcome by a novel scheme worked out by Charles R. Crawford. With a 6-hp. Fairbanks-Morse gasoline upright single-drum hoist, he first pulled the supplies off the barge to the shore. Then, by fastening the donkey to a 12 by 12 'dead man' imbedded in the snow, the supplies by relays were hauled up the face of Shoup's glacier, across that and Columbia glacier, to an altitude of 4500 ft. From there, the material was lowered to the mine workings. The freighting cost was 3c. per lb. from the beach to the mine.

Work on the cross-cut of the Valdez Mining Co., operating claims on Valdez glacier eight miles from Valdez, is being continued. The first adit is 125 ft. long. From it a winze 50 ft. deep has been sunk on the orebody, and 50 ft. of drift run from the bottom of the winze. Seventy feet of the cross-cut remains, which will tap the 6-ft. lode 375 ft. below the surface. Johnson and Erickson, lessees on the Williams-Jentzler property on Mineral creek, are continuing development. George Calligan is working a stringer in the same district and plans to make a shipment soon.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

SLUMP IN MYSORE SHARES; PAST RESULTS OF THIS GREAT MINE, GEOLOGICAL FACTS, AND FUTURE.—SHAMVA AND ELDORADO MINES.

The London market has had a bad fit of the nerves this week, owing to a slump in the quotation of Mysore shares. For several days the price dropped ominously, and many 'croakers' predicted the coming of the end. The Mysore is the oldest and most prosperous of all the gold mines in the Kolar district in Central India, that have been managed so ably by John Taylor & Sons. The orebodies are found in the pre-Cambrian rocks, and they have fulfilled Malcolm Maclaren's contention that ore in such rocks is likely to persist to great depths. The Mysore has been paying dividends steadily since 1886, and has distributed $35,000,000, earned from a production of $70,000,000, extracted from 3,900,000 tons of ore. The yield in 1913 was $4,300,000 from 302,662 tons, and $1,800,000 was distributed as dividend, being at the rate of 125%. The ore reserve is sufficient to keep the mill employed for four years, and it is no wonder therefore that the shares stand at a high premium. For some time the quotation of the 10 shilling share has been over £5. Last week the first movement for a long time took place, and every day saw a fall of 5 shillings, until £3 15s. was reached. The directors issued a circular assuring shareholders that nothing had occurred since the last general meeting to warrant any gloomy forebodings. It is true that developments have been practically suspended during the last four months, but that was because the drought caused a shortage in hydro-electric power. The geological formation encourages the theory of alternating poor and rich zones, so that shareholders do not as a rule get scared when development gives reduced results. A glance at the vertical longitudinal sections at the Mysore and its neighboring mines, the Champion Reef, Nundydroog, and Ooregum, shows that these 'alternating zones' are misnomers, and that a more satisfactory explanation of the formation is to describe the richer zones as a series of flat-pitching ore-shoots. The shoots in the Mysore pitch northward into the ground of the Champion Reef, but unfortunately for the Mysore there are no known orebodies to the south to pitch into its ground in depth, so that when a 'zone of impoverishment' is encountered in the bottom workings at the south end, the chances are that no further 'zone of enrichment' will be cut. That John Taylor & Sons are fully aware of this formation is shown by the fact that exploration outside the southern boundary is being conducted from the 2100 and 2300-ft. levels of the Mysore. No orebody was ever found in this area by exploration from the surface, but it is just possible that there may be one there that does not outcrop. As a matter of fact, other orebodies that do not outcrop have been found in this great lode, farther to the north, and consequently another may be found. Unfortunately, however, no results have been obtained as yet.

Rhodesian mining operations are in the hands of a few big corporations, the directors of which do as they like with the shareholders and the public, both financially and technologically. The Shamva mine provides an instance. This is controlled by the Gold Fields Rhodesian Development Co., which handles the Rhodesian interests of the Consolidated Gold Fields of South Africa. The Shamva orebody is a big one, and as it outcrops on the top of a hill, it can be worked cheaply. The Gold Fields people heralded it as a 'banket,' thinking that the magic of that name as known on the Rand would boom the shares on the market. The same thing was done by the same promoters in connection with the Eldorado mine, which is in the same district of Rhodesia. The deposit is not a pebble-bed at all, but a breccia or agglomerate. Another questionable point of policy at the Shamva has been the sudden stoppage of development at depth just at a time when the persistence of the orebody in depth became an interesting topic for discussion. On the prospect level, the orebody is 740 ft. long and 88 ft. wide, averaging 3.8 dwt. per ton; on No. 1 level the corresponding figures are 920 ft., 110 ft., and 4.14 dwt.; on No. 2 level, 820 ft., 97 ft., and 6.77 dwt. Work on the fourth level was stopped when 150 ft. of the length was proved, measuring 62 ft. wide and averaging 5.36 dwt. per ton. The cause of the stoppage is alleged to be lack of compressed air, but it is also stated that winzes are being sunk from the No. 3 level to a depth where a No. 5 level can be started. The total reserve is reported at 2,405,796 tons averaging 5.01 dwt. gold per ton. A mill containing 56 Nissen stamps and 10 tube-mills has been erected, capable of treating 50,000 tons per month. The first portion was started in January of this year, but the plant was not running at full capacity until May. The remarkable feature is that there is a big discrepancy between the assay-value of the feed and tailing, and the actual yield. This has been going on all the time, and the shortage of yield is perplexingly great, far too great for the absorption of gold by the plates and held in the circulating cyanide solutions to account for it. People are asking whether screen sampling is regularly done, or whether the assay-value of the feed is really the estimated assay-value in the stopes. Whether with the object of investigating this shortage or otherwise, the amalgamating plates have been removed, and it is stated that the extraction by cyanide alone is as satisfactory as by the two processes. But these metallurgical questions are not sufficiently illumined to warrant any discussion here.

The Eldorado mine was mentioned in the above paragraph. The details of the ore deposit here have been kept secret, but geologists who have had the privilege of going underground state that in some places very rich ore was found. Its presence was never divulged, so that no rush of prospectors ever occurred. The free prospector is disliked by the powers-that-be in Rhodesia. It is only the tributer who is ready to accept the crumbs that fall from the rich man's table that is encouraged. The Eldorado appears to be reaching its end. Bad mining methods caused a collapse of part of the upper workings some time ago, and such ore as can now be extracted from those levels is mixed with much worthless rock. One of the lodes, called the Parallel Reef, has proved valueless below the No. 8 level. On the main lode the orebody is only 65 ft. long on the No. 13 level, having shown a continued shrinkage from the No. 9 downward. The ore sent to the mill has been reduced, as well as the grade. Ore reserves mention 14 dwt. as the content, but the ore fed is of an 8-dwt. grade. The reserve stood on June 30, 1914, at 55,000 tons averaging $15 per ton. The main shaft is down to No. 15 level. On No. 14 the cross-cut should open the lode at any time. The main winze east from No. 13 level is down over 38 ft. and assays $17 over 55 in., the face showing free gold.

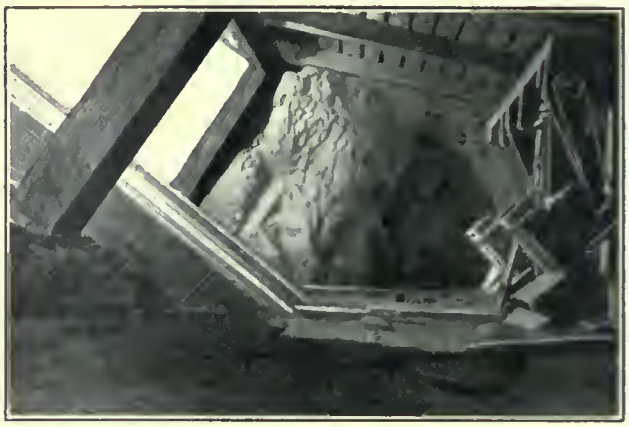
HOUGHTON, MICHIGAN

WIDE USE OF ONE-MAN DRILLS IN THE COPPER COUNTRY.—QUINCY AIR-BLASTS.—EFFICIENCY CAMPAIGN.—STRIKE NOTES.

Illustrative of the recent tendency to replace old-fashioned heavy machine-drills by light one-man and water-Leyner drills, the copper country manager of one mine machinery house states that, since the latter part of 1911 he has sold 2000 drills, which is nearly equal to the total number of drills in use in the Lake Superior copper mines—this in spite of the practice of mining companies of manufacturing their own repair parts. The Leyner is the most popular all-around driving and stoping drill, being a 150-lb. machine, the pioneer of the mounted hammer types to give satisfaction, and the Calumet & Hecla even uses it for driving inclined raises (although most other companies use stoper drills for raising); the Quincy used the 'Baby Leyner,' a ninety-odd pound machine, for driving and stoping. Since being taken over by the Ingersoll-Rand Co., the Leyner drill is made with a 'butterfly' valve, which is an improvement over the spool variety of air-thrown valve. The little jackhamer, also with a 'butterfly' valve, a self-rotating 'plugger' drill, has proved popular in shaft-sinking (as in the Michigan iron mines), and is used for block-holing large masses underground. But the most important result of the advent of the jackhamer is the discoveries made in the foot-wall of old stopes on account of being able to dig after showings of copper conveniently, where tripods and heavy drills would be quite awkward. When in the days of heavy drills a little showing of copper was noticed in the foot-wall, the mining captain sometimes gave orders to "carry a tripod and drill up there and see what it is"; but more often he did not, as the foot-wall was liable to be rough climbing. The jackhamer, weighing 40 or 50 lb., is just the drill for prospecting such places, and some of these insignificant little showings in the foot-wall of amygdaloid lodes are leading the way to valuable deposits, in many places large 'chambers' of rich copper as wide as the original lode. The old Wolverine mine is considerably prolonging its life in just this manner, while one of the officials at the Quincy has hopefully stated that that famous mine "bids fair to produce as much copper, working from the bottom up to grass roots, as it produced from the grass roots down to bottom." The Quincy has 110 jackhamers, which shows the extent to which foot-wall exploration is being carried. Incidentally, the Quincy is being considerably bothered by air-blasts, which are increasing in frequency, often shaking the ground in Hancock and Houghton quite noticeably. (On one occasion, a gentleman in Houghton, feeling a particularly heavy air-blast, dropped in at his brokers and sold some Quincy stock, guessing rightly that it would depress the stock a little.)

The Calumet & Hecla's efficiency campaign, particularly as regards underground details, is producing wide results in the copper country. In addition to considerably reducing the cost of mining at the lower-grade mines of the Calumet & Hecla interests, such as Isle Royale and Superior, so that these properties can pay dividends, the other companies in the district are getting into the efficiency habit, and some of them employ men to direct their underground affairs who have been trained by the Calumet & Hecla's efficiency department. Thus the Victoria mine, which has struggled for so many years with the disadvantages of very lean ore (or 'rock'), and of being four miles off the railroad in rough country (and which, in fact, has only managed to exist by virtue of practically free compressed air from its rock-bound, water-entraining air-compressor), recently hired as mining captain a young man who had learned underground methods with the Calumet & Hecla. This new foreman discovered that part of the time the Victoria had been in the lode and part of the time groping out of the lode, so that now with more discerning superintendence the Victoria is doing better than for a long time and opening good ore. The seat and centre of the Calumet & Hecla's efficiency movement is at its Superior mine, just south of Houghton.

The superintendent for the Superior Copper Co. is also chief efficiency engineer for the Calumet & Hecla companies, and he tries out in his mine most of the efficiency innovations before they are adopted on a large scale; furthermore, if in introducing a new method, say at Calumet, the miners declare "it can't be done," the superintendent of the Superior will go up and do it for them himself, being an expert at handling a drill and at practical mining. It is, of course, known that too autocratic 'efficiency' helped to bring on the disastrous miners' strike, but as one mining man expressed



LOADING STATION IN A MICHIGAN COPPER MINE.

it, "the strike taught both sides a lesson, and things are going better now." In the light of later developments, it is realized that what really broke the backbone of the strike was the spectacular kicking out of Charles Moyer by the enraged mining men and citizens, since such a procedure represented action that the striking miners could understand and relieved the tension, being a typical Lake Superior method of dealing with trouble. As to whether general manager James MacNaughton of the Calumet & Hecla was a member of the 'serenade party,' as Moyer claimed, or merely his brothers, even those on the inside of things say "no one knows." It is admitted, however, that Moyer was lucky to get no worse than he did.

BUTTE, MONTANA

EFFECTS OF THE WAR IN EUROPE ON COPPER MINES AND WORKS; MANY UNEMPLOYED; BUSINESS IN BUTTE VERY DULL.

Labor troubles at Butte, which are always with us to a greater or less extent, have sunk into insignificance in the light of the new menace, the European war. The war crisis has had an immediate and serious effect on the mining industry at Butte. The copper companies claim that there is no market for their product, and in consequence are ordering wholesale closing of the mines with their dependent industries. The Great Falls smelter has been ordered closed entirely; the Anaconda smelter has laid off a large force of men, and has stopped all work on construction and improvements. At least half the Butte mines are closed, and it is predicted that within a week most of the rest will close. Nearly all properties in which prospecting and development work was in progress have been closed, because of the tightness of the money situation, and the uncertainty of future conditions. The East Butte Copper Co. has closed both its mine and reduction works, which affects not only this property, but some smaller properties which ship to the Pittsmont

smelter. One of the banks at Butte has already closed its doors, and others have issued notice demanding time on all savings accounts. The whole community is in an unsettled and scared condition, undoubtedly worse than at any time in Butte's history. The stores are idle, no purchases being made, except those absolutely necessary. Of course there is no trading in stocks, or any speculative investment of any kind. The town is full of idle men, who spend their time reading war bulletins, and discussing gloomily the foreboding situation. A large number of technical men connected with the mining industry here, who had planned to attend the meeting of the American Institute of Mining Engineers in Salt Lake City on August 10 have found it necessary to cancel their arrangements, either because they did not feel justified in spending the money required for the trip, or because business cares at home demanded their presence here. It is expected, and it is to be hoped, that the idle miners and others who have been thrown out of employment can scatter to the agricultural areas and secure work in the harvesting of the crops of Montana, which, fortunately, are large and extensive. As this situation has come upon us like a thunderbolt, we are far from adjusted to it, and are able to draw no conclusions, nor make any predictions.

DEADWOOD, SOUTH DAKOTA

Leaching Plant for Jungle Copper Ores.—Titanic Gold Mining Co.'s Work.—Homestake Company's Recreation Hall Opened.

Owners of the Jungle mine, in the Custer Peak district, announce they will proceed immediately with the erection of a copper leaching plant of 30 tons daily capacity, in which the details of the process will be worked out preparatory to the construction of a much larger unit. A portion of the machinery and equipment has been secured second hand in the Black Hills, and the balance will be delivered promptly by the manufacturers. The property shows a large quantity of oxidized ore which laboratory tests indicate can be successfully leached. John H. O'Brien, of Roubaix, South Dakota, is superintendent.

At the annual meeting of the Titantic Gold Mining Co., held at Deadwood, it was announced that $22,000 had been spent during the past year in development and equipment of the Iron Hill mine, at Carbonate camp, and in the purchase of the Albe fraction, which consists of less than two acres. The work included erection of a shaft-house, installation of hoist, air-compressor, Jackhamer drills, etc., sinking 267 ft. (making the shaft 300 ft. deep), and driving 290 ft. of drifts and cross-cuts. Ore was cut in several places, but not in any great quantity. At the present time drifts are being driven east and west on the 100-ft. level, following the main crevice. On the 150-ft level a cross-cut is being driven south in which some high-grade ore has been found. On the 300-ft. level, a diamond-drill will immediately be installed, and a number of holes put in different directions. This level is connected with the old Iron Hill workings, giving good ventilation. Fred Schnauber, of Yankton, South Dakota, was elected president, and W. S. Elder, of Deadwood, secretary and general manager.

On July 27 the swimming pool and shower baths in the basement of Recreation hall, at Lead, were opened to the public and thoroughly enjoyed by hundreds of people. Stocks of bathing suits in the stores at Lead were quickly sold out, for the opening came at an opportune time, during a spell of extremely hot weather, and the result was that seemingly everyone wanted to indulge in a plunge. The baths will be opened daily, excepting Sunday, a part of the time for men, other times for women, and twice a week for mixed crowds. The Homestake company constructed the building at a cost of over $250,000 for the free use of its employees.

TORONTO, ONTARIO

Work at Porcupine Crown Mine.—North Dome Shut Down.—Nipissing Doing Custom Work.—La Rose Prospects.—Tough-Oakes Mine.

During the past few months the Porcupine Crown company has been doing a large amount of development work in an effort to find a continuation of the veins which were cut off by the faults to the south of the orebody, and below the 400-ft. level. So far, these efforts have been unsuccessful, and the indications at the south end of the property are considered promising. In order to assist the management in planning the development, an economic geologist has been employed, and he is at the present time making a study of the deposit. The mill is only working six days per week, and the daily tonnage treated is below capacity. The Company does not desire to do more than earn enough to pay dividends. The comparatively small tonnage of ore in reserve at the present time probably represents a little less than two years supply, but the mill is a disturbing factor, and the Company is extremely anxious to develop new orebodies.

The Temiskaming Mining Co. of Cobalt has made an application for an order for the winding-up of the North Dome property. Two years ago, the Company purchased control of the North Dome, and spent a considerable amount of money in development. It only succeeded, however, in opening up three small shoots of low-grade ore, which would not justify the erection of a mill, and the property was subsequently closed. The Temiskaming is stated to be a creditor to the extent of $85,000.

The Nipissing company's high-grade plant is treating considerable custom ore in addition to the Company's own output, all of which is shipped from the camp in the form of bullion. The ore is purchased outright by the Nipissing, and the bullion goes out under its own name, so that the apparent production from Kerr Lake and La Rose, in particular, is less than would appear from the published returns.

The La Rose company has also taken an option on outside properties, and is now developing the Kensy claim in Boston township, near Swastika. The surface showing is small, but is reported to give satisfactory assays. The financial statement sent out with the June dividend shows that the surplus, which stood at $1,528,776 on December 31 last, has been reduced to $1,359,920. The decline of this once famous property is one of the most interesting features of the present situation in Cobalt. The La Rose was the first discovery in the camp, and for a long time was the largest producer. It is now, however, practically worked out, and officials of the Company entertain only a slight hope for the continuance of its productiveness. It is understood that the consulting engineer has recommended the closing down of some of the properties in the immediate future. To date, the La Rose Consolidated has produced approximately 2,500,000 oz. silver, valued at $11,500,000. Of this amount, the profit would be roughly $6,500,000. While it is possible that other discoveries may be made, the mine has been developed in an aggressive and conscientious manner, so that little hope can be held out of the Company maintaining its position much longer.

H. H. Johnson, consulting engineer of the Tough-Oakes mine in Kirkland Lake, estimates that the developed ore has an average value of $32.60 over a stoping width of between 4 and 5 feet. He also states that by January, the mine should have three years' supply of ore developed for a mill having a capacity of 30,000 tons per year, and that the estimated net profit per annum will be $750,000. Excavations for the new mill have been started and orders have been placed for machinery. Since the commencement of operations, up to May 19, the mine had produced a total of $220,000. At present underground work is stopped for lack of power.

WASHINGTON, D. C.

PHOSPHATE LAND LAWS.—BILL TO QUIET TITLE TO LANDS LOCATED BEFORE 1912.—REMEDIAL LEGISLATION REGARDING OIL AND GAS LANDS.

Progress is once more reported on the bill to validate location of phosphate deposits. This has been up in Congress since 1908, and while it seems simple, it has met many snags. It has now passed the Senate and has come out of the House Committee on Public Lands with a favorable report, and therefore is in a good position to pass when the House gets into a mood to rush small bills through. This may occur in this summer session. The bill as reported purports to validate locations of deposits of phosphate rock on the Pacific Coast heretofore made in good faith under the placer-mining laws. The particular occasion for the passage of the bill is the uncertainty that existed prior to 1912 of the right to make entry for lands containing phosphate. Prior to that date it was the practice of the Department to patent locations made under either the lode or the placer mining laws. In 1912 the Department of the Interior decided that a deposit of phosphate rock, confined by well defined boundaries, constituted a 'vein or lode of mineral-bearing rock in place,' and that such a deposit was subject to disposition only under the provisions of the lode-mining laws. To permit the locations made in good faith under the placer-mining laws prior to the 1912 decision to pass to patent, and to quiet title to those receiving patents under the placer-mining laws prior to 1912, the pending bill offers relief. The bill has the approval of the Department of the Interior. In a letter to Scott Ferris, congressman from Oklahoma and chairman of the Public Lands Committee of the House, A. A. Jones, first assistant secretary of the Department, says: "Where the asserted placer-mining locations on the phosphate deposits antedated withdrawals and where no conflicting adverse lode locations are involved, this Department perceives no objection to the confirmation of such locations and the authorization of the issuance of patent thereon. In the absence, however, of remedial legislation these locations cannot be passed to entry and patent. The only relief the Department, under the condition of the law as it now exists, is able to extend to such placer locators is to permit them after a modification of the outstanding phosphate withdrawal has been secured, to re-form their locations or make new locations under the lode-mining laws, and thereupon to proceed to entry and patent. Prior to 1912 it was the practice of the Department to permit locations under either the lode or the placer-mining laws to pass to patent, but consideration of the Harry lode mining claim, supra, and the position taken by the federal courts in the decisions above mentioned, precluded the further pursuit of such a practice. Since that time no patents have been issued to placer locators. The remedial legislation in the bill is therefore essential, and, in the opinion of this Department, should be enacted."

An agreement has finally been reached by the House Public Lands Committee and the Interior and the Navy Departments on the bill to provide for the temporary development of oil and gas lands, particularly on the Pacific Coast, in dispute between the Government and private claimants. The proposed law, as stated, would allow the present occupants of the lands whose title is contested by the Government to develop and protect the oil resources under agreements with the Secretary of the Interior which would impound or divide the proceeds of the development pending the settlement of the disputes over the title. The amendment agreed upon provides that the money accruing to the United States under the agreement dealing with land in naval petroleum reserves shall be set aside in a separate fund for the use of the Navy under the control of Congress.

NEW YORK

EFFECT OF THE WAR ON COPPER, TIN, CYANIDE, AND MANGANESE.—CHILE COPPER CO. *v.* ANTOFAGASTA & BOLIVIA RAILWAY.

What will happer to the copper mines has been the chief topic of interest all the week. The obvious thing, of course, is that, for the present, copper shipments to Europe must come to a halt, as ships are not available to carry it, even if any European consumer could conceivably wish to buy. This cuts off the market for over half the American output, and the principal producers have promptly moved to meet the situation by cutting down their output, as chronicled in 'The Mining Summary.' In the Lake Superior district the Copper Range will reduce its output, but the Calumet & Hecla is reported to plan to continue full time for a month yet. The cases are not quite parallel, as Copper Range sells most of its copper abroad, while the C. & H., as it is generally called, sells the larger part of its copper in this country. The collapse of the copper market brings special individual hardships, as well as the general ones. The Superior & Boston at Globe has just succeeded in pushing itself into the dividend-paying class, and for the first time in its history the financial year will show an operating profit. Profits to September 30 were expected to be $30,000, while a shut-down would entail a monthly loss of $6000, and copper at 12c. per pound corresponds to about $4000 per month operating loss. Another company which is hard hit is Granby, which has had uphill progress for the last few years. The new smelter at Anyox began turning out copper in April, and produced 1,000,000 lb. during June. The Phoenix plant has been shut down, but the smelter at Anyox will be kept going, as it has only just got running in good shape and it would be a pity to have to stop so soon. Companies everpwhere will use the slack interval to make repairs and put their plants in good shape.

The war has completely disorganized the supply of some metals and minerals. Tin has gone up to 60c. per pound already. Most of the tin comes from the Straits Settlements and comes through the Mediterranean to England to be reshipped to this country. The chances of forwarding regular shipments through the Mediterranean for some time to come are remote in the extreme, and tin has correspondingly gone up. Presumably tin plate for making cans for preserving food will be in strong demand. It would be quite possible to send tin to America by way of the Pacific, of course, but the lines are indirect, the freights high, and the time required longer. Cyanide is another commodity which is worrying mining men. A large part of the supply comes from Germany, and regular shipments are stopped. Some firms with plants at Niagara Falls are engaged in the manufacture of cyanamide, which is largely used as a fertilizer, and have for some time been urging the use of their product as a substitute for cyanide. If it proves satisfactory, this may serve to save the situation. The war has also cut off the ferro-manganese supply of American steel-makers. The subject of this mineral was discussed at some length in this paper a year ago. The United States Steel Corporation is said to have a good supply of manganese ore on hand, and will at once begin to turn it into ferro-manganese, and it is to be hoped that the business, once established, will continue. There are large deposits of excellent manganese ore in California, and their development could be undertaken.

The Chile Copper Co. is engaged in a lawsuit with the Antofagasta & Bolivia railway over the water rights to the river Loa, which is the source of supply for both companies. The river crosses the railroad at some distance from the coast, and the railway built a dam and developed the water supply which serves all the western end of its line. Those familiar with the country say there ought to be plenty of water for both companies if properly conserved.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Fairbanks

From Chitina to Fairbanks is 325 miles, and on July 13 R. Sheldon and three others arrived in his Ford automobile, having covered the distance in 34 hours 50 minutes.

Nome

The Ben Bernard dredge at the mouth of Anakovik river has been started. The dredge moved from Peluk creek to Anakovik by the company has been operating successfully for several years.——The Union Construction Co. of San Francisco is rushing work on the Bangor dredge for Cole, Mitchell & Brower. Forty men are employed.

ARIZONA

Cochise County

Wages have been reduced 10% at the Copper Queen and Calumet & Arizona smelters at Douglas on August 6. This affects 2000 men. There were 500 men laid off. These companies' miners also had a similar reduction.

Gila County

At the Miami mine, one shift has been stopped, and only three of the six units of the mill are working.

Greenlee County

The Shannon Copper Co. reports as follows for the second quarter of 1914:

Ore treated, tons	67,464
Copper production, pounds	3,118,156
Gold, ounces	420
Silver, ounces	20,702
Average cost of producing metal, cents per pound	12.695
Net profits	$40,952

Pinal County

The second quarterly report of the Ray Consolidated Copper Co. shows the following:

Mine development, feet	31,515
Cost of mining, cents per ton	61.741
Ore milled, tons (equal to 8396 tons per day)	764,010
Average copper, per cent	1.786
Recovery by concentration, per cent	68.69
Cost of milling and coarse crushing, cents per ton	50.651
Smelter output, including ore treated direct, pounds	19,062,555
Net profit	$959,491
Dividends paid	545,364
Net surplus	414,130
Copper on hand, in transit, sold and unsold, pounds	25,819,671

The output, recovery, and costs were an improvement on the previous term.

Yavapai County

About 300 men have been dispensed with at the United Verde mine and smelter at Jerome, in order to reduce the copper output.

CALIFORNIA

Eldorado County

The Big Cañon mine has been unwatered, and work is to be started proving the ore between 600 and 700 ft.——Three feet of fair ore has been opened in the Crusader mine near Eldorado.——Electric plant for the Shaw mine is nearing completion.

Placer County

Negotiations are proceeding in connection with the Placer County Properties Co. ground near Iowa Hill, the amount being given as $35,000.——Another 40 acres of dredging ground at Gold Run is to be bought by Lawrence Gardella, of Oroville. Lumber for the new dredge has been ordered.

Shasta County

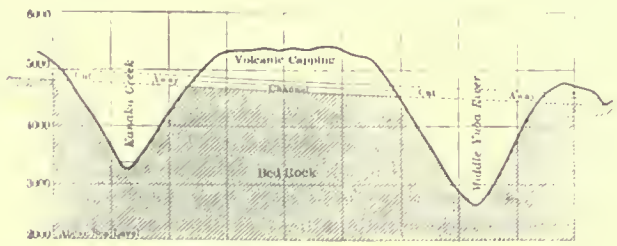
On account of the war in Europe the Mountain Copper Co. shut down its Iron Mountain mine on August 6, laying off 350 men. The Hornet mine is still worked. The smelter at Martinez is shut down.——Work has been suspended at the Balaklala mine.——The Golinsky copper claims, four miles from Redding, were under bond to a German syndicate for $100,000, but the deal is now temporarily off.

The Mammoth Copper Co. has decided to keep two furnaces in blast, and all employees will get at least 5½ days' work per week. There will be no reduction of wages, and married men on vacation need not pay rent for Company houses, which their families are occupying.——The Mountain Copper Co. will also remit rent due and give good credit at its store.

Sierra County

The Croesus mine is opening well, 35 men are employed, the mill is running at full capacity, and the monthly output is about $30,000.——The Sierra Nevada gravel mine at Forest is to be reopened. The property consists of 270 acres containing a good channel.

The ancient auriferous gravel channels of this county are discussed by Mark N. Alling, of Downieville, in the July *Bulletin* of the A. I. M. E. Sierra county is about 10 miles long, east and west, and about 20 miles wide. The summit of the Sierra Nevada mountains passes through the central portion of the county in a northerly and southerly direction. All the mines lie on the western slope of the mountains. In the extreme western part of the county the rocks are principally black, highly metamorphosed clay slates, designated by government geologists as the 'Delhi slates.' They are



EFFECT OF MODERN EROSION ON ANCIENT DRAINAGE SYSTEM, SIERRA COUNTY, CALIFORNIA.

underlain by granites which are exposed in the bottoms of the deep cañons. Porphyry and diorite dikes are common in the slates. A few good mines have been found in this formation. Lying just east of the Delhi slates is a zone about 10 miles wide, consisting of alternating belts of Calaveras formation and serpentine or amphibolite. This zone parallels the course of the Sierras, flanks the range, and is the line of weakness. It is highly fractured and mineralized and forms what is known as the 'Father Lode' of California, in contradistinction to the Mother Lode, which occupies a similar position relative to the range in Amador, Calaveras,

Tuolumne, and Mariposa counties. In this zone are found most of the quartz mines and practically all of the gravel mines. Next to the east lies a zone of quartz porphyries, granites, slates, and occasional small dikes of serpentine. Here are found the Sierra City quartz mines, some of which have been large producers. The zone is from three to five miles in width. Between the Sierra City quartz-porphyry zone and the summit few mines of importance have been found. Beyond the summit no mines are found until the state of Nevada is reached. The lode mines and ancient channels of the districts are described in an interesting manner. Some of the former are yielding good returns, notably the Tightner, Red Star, Rainbow, and Sixteen to One properties. In the past, ancient channels of the county have yielded from $150 to $500 per linear foot. In large channels, gravel worth $1 per cubic yard, if free, will about pay for extraction. Cemented gravels cost from 50c. to $1.50 more per ton to handle than free gravels. In the Downieville-Forest City-Alleghany district, gravel averaging from $1.50 to $2.50 per cubic yard is considered good 'pay.'

In the introduction to his paper, Mr. Alling made the following remarks: "A few years ago, gravel mining in the ancient river beds of Sierra county was the principal industry of the county. Operating drift mines were numerous and many large hydraulic mines were in action. Eventually the state laws put an end to hydraulic mining, it being claimed that the silt carried down the streams to the valleys filled the rivers and caused winter floods, which were damaging to the surrounding farms. The ancient river deposits which could easily be found were, in the course of 40 years, worked out or practically so. The prohibition of hydraulic mining was a severe blow to the industry in general. The deposits were not developed and the gravel-mining industry practically stood still for many years. In Sierra county, nearly all the hydraulic mines were at the points where the ancient channels were exposed to view by reason of the modern stream erosion, or, in the miner's language, where the channels enter or 'break out of' the ridges. The claims covering them also covered large areas in which were long segments of lava-capped channels, suitable for drift mines, and the points being hydraulicked were usually the controlling points of attack. Men who have followed hydraulic mining for any length of time seldom are content to work a drift mine. Knowing the great value of their deposits and feeling that they had been robbed by the state, these men have stubbornly held to their claims. The gold that is carried in these gravel-channel deposits is more or less scattered throughout the depth and width of the deposit; the percentage that can be recovered by the process of driving ranges from 50 to 75 of the total. In hydraulicking, practically all of the deposit is put through the sluices, and as the cost per cubic yard is only about 10% of the cost of driving, the deposits, if classed as hydraulic mines, are much more valuable than if classed as drift mines; hence the old-timers have held their claims (now worthless as hydraulic mines) at prices which the drift-mining industry could not stand; and such mines are still intact. Gravel deposits formerly valued at a great price have reverted to the Government. Some of the claim owners, realizing the truth, have sold their mines for reasonable figures, and many of these properties are now being reopened. But there is another and important source of future drift mines. Only the deposits which could easily be discovered have been found. There are many unworked segments of ancient channels in this rich district; some have been discovered in a general way, but never exactly located or traced through the country; still others have been partly developed, requiring the investment of more money than the owners possess. The district is isolated, timbered, and brushy (especially in the vicinity of the moist-gravel deposits), and hence the more difficult forms of prospecting have been left to the coming generations. The long period of comparative inaction in the gravel-mining industry has given rise to the common opinion that the gravel deposits are all worked out; but such is not the case. The field is young and large, and yet to the stranger passing through the county for the first time the impression is given that the district is an old and exhausted one. This is principally due to the fact that in the boom days, when the shallow placers were yielding fortunes for the thousands who worked them, large towns sprang up, only to be deserted in whole or in part upon the exhaustion of the shallow placer deposits and the desertion of the hydraulic mines. Following the exhaustion of the discovered placers, and the suspension of hydraulic mining, came the search for the sources of the gold. Mining companies began to reopen the old drift mines, exploring for the quartz veins, and with such remarkable results that the annual gold output of the county was increased last year by about $1,250,000. Other companies are now exploring for the undiscovered channel segments."

COLORADO

Clear Creek County

The Chamberlain Ore Co., at Georgetown, was only paying 40c. per ounce for silver, the balance to be settled later; but afterward refused to buy any more ore.——The Burleigh mill is shut down indefinitely.——An adit is being driven in the Capital Central mine to cut a vein at a depth of 200 ft.——Treatment of the low-grade ores of upper Clear Creek county by flotation and cyanidation is suggested by Edward J. Wilcox.

Teller County (Cripple Creek)

The Vindicator mine produced 2250 tons of ore on company account, and 800 tons on lessees' account in July. The respective gold content of shipments was about 2 oz. and 1 oz. per ton, ore from 1600 ft. making the former high value.——Rainfall of the district in July was 9.12 in., a record, and compared with an average of 17.07 in. per year.——A new hoist is being installed at the Eclipse mine of the El Oro company.

IDAHO

Bonner County

At the Marguerite mine near Hope, a contract has been let for 200 ft. of development work in extending the lower adit. Ore should be cut at between 500 and 600 ft. A good deal of gold-silver ore has already been opened. The Bonner Mining Co., of Spokane, controls the property.

Shoshone County

The Montana-Idaho Copper Co. has recently been formed, with Otis Hall, of Spokane, as general manager. It owns eight claims near Adair, and the Monitor mine. It is proposed to drive an adit 7500 ft., giving a vertical depth of 1800 ft. below the collar of the Monitor shaft. Laterals from the adit will open the orebodies of surrounding claims, and furnish an outlet for ores to the Chicago, Milwaukee & St. Paul railway. This is one of the most important works projected in the Coeur d'Alene district. E. P. Spalding, of Spokane, is consulting engineer.

The Caledonia Mining Co. held its annual meeting at Kellogg on August 4. A unit of the Bunker Hill & Sullivan mill is working one shift on Caledonia ore, treating 100 tons. The balance sheet shows about $45,000 in the treasury. Profit on the July output of 700 tons of concentrate was 1.5c. per share on the capital of 2,600,000 shares.

There are 25 defendants, including individuals, a corporation, and a state, in the action of the Marsh Mining Co. to condemn part of the surface ground of the Never Sweat lode mining claim near Burke. The area in dispute is 3.382 acres.

Lemhi County

(Special Correspondence.)—The Salmon River Power &

Light Co. has been formed mainly by Colfax and Spokane, Washington, people. The Citizens' National Bank of Salmon also subscribed for shares. This Company takes over the property of the Lemhi Power Co. A new hydro-electric plant is being constructed 15 miles above Salmon.——Two new

GOLD DUST PROPERTY, NEAR LEESBURG, IDAHO.

dredges are to be built soon, making five in the county.——Good lead and copper ore is being mined from Brough's and others claims on Phelan creek.——At Gilmore the Allie and Latest Out are the principal lead-silver ore shippers.

Salmon, August 1.

MICHIGAN

Houghton County

After unloading coal at the Isle Royale mill last week, the steamer *Gogebic* went to Point Mills to load stamp-mill sand for the Ontario Paving Block Company of Ohio. Over 15,000 tons of this sand has already left the copper country this season, and the demand is likely to increase. It is possible to load a boat with 5000 tons in 10 hours.

The Wolverine Copper Co. reports as follows for the year ended June 30, 1914:

	1914.	Changes from 1913.
Copper produced, pounds	3,435,459	— 4,914,853
Total revenue	$484,061	— $842,439
Expenses	388,708	— 336,278
Net profits	$95,353	— $506,161
Construction and strike charges	14,277	+ 14,277
Balance	$81,076	— $520,438
Dividend	.....	— 600,000
Surplus	$81,076	+ $79,562
Previous surplus	748,034	+ 1,514
Total surplus	$829,110	+ $81,076

The general balance sheet as of June 30 shows cash in hand of $20,558, assets of $905,503, and balance of assets $829,109.

While a good deal of the copper output of this district is sent to Europe, the bulk of domestic business is held by the Lake Superior mines. There will be no curtailment of metal production on account of the war. A large number of Europeans are employed there, but not many are leaving to take part in the European war.

All exploration and development work at Calumet & Hecla subsidiaries, as well as preparations to increase production, have stopped.

In July there were 256 vessels bound up, and 209 bound down, through the Portage Lake ship canal. The amount of freight up was 251,701 tons, of which 200,119 tons was coal, also 10,750 passengers; the freight down was 86,018 tons, of which 7489 tons was copper, and a large quantity of grain.

MISSOURI

Jasper County

Owing to the war in Europe, and the general condition of the spelter market, higher prices are predicted at Joplin.

MONTANA

Silverbow County

The Bullwhacker mine and leaching plant has been shut down indefinitely by a suit brought in the district court by Clark Bros. & Klein, brokers, of Spokane, for the recovery of $121,000 loaned on promissory notes, together with an attorney fee of $24,000. The money was spent on the new plant, and $20,000 more would have made the plant a profitable concern.

Work has been suspended at the Butte-Ballaklava mine.——On account of the State's Saving Bank closing its doors, development at the Tuolumne, Pilot, and Butte Main Range mines will probably be stopped, as this institution held funds for this purpose.

NEVADA

Esmeralda County

A Chilean mill is to be erected at Gold Crater, east of Goldfield, by the Gold Prince Mining & Leasing Co. A good tonnage of ore has been opened to 265 ft.——McGucken, an organizer of the I. W. W., was prevented from making an inflammatory speech at Goldfield last week by the sheriff, and left for Tonopah. He said that Goldfield did not appeal to him as a particularly favorable field for his endeavors and those of his following.

Nye County

John G. Kirchen, president of the Nevada Mine Operators' Association, telegraphed Senator K. Pittman on August 7 urging Congress to pass an act authorizing the Treasury to purchase 25,000,000 oz. of silver on the last market quotation. It is urged that unless this is done the mines will be unable to continue operations and thousands of miners will be thrown out of employment. Probably the mining companies will store their silver, which totals about 1,100,000 oz. per month, and wait for favorable prices.

A cloudburst at Manhattan on August 7 did a great deal of damage to placer mines and the town.——Shipments of $10 ore are being made from the White Caps mine to the Western Ore Purchasing Co. Development underground is adding good ore to the reserves.

Storey County

A 200-ton plant to treat old Comstock tailing by a new process, 4½ miles north of Dayton, has been erected by the Metals Recovery Co., in charge of Andrew J. Trumbo.

White Pine County

The Nevada Consolidated Copper Co. reports as follows for the second quarter of 1914:

Overburden stripped, cubic yards	1,162,049
Cost of removing overburden	$371,301
Steam-shovel mining, per cent of total ore mined	95
Ore milled, tons	831,589
Average copper content, per cent	1.53
Ore milled for Giroux Consolidated, tons	55,879
Copper output, pounds	14,322,807
Net earnings	$614,818
Dividends	749,796
Deficit, including depreciation, ore extinguishment, etc.	364,216
Surplus of assets over liabilities	$7,071,850
Copper on hand and in transit, sold and unsold, lb.	23,276,016

Copper production of the Nevada Consolidated has been reduced about 50% on account of the war in Europe.——A study of the Ruth mine of the Company is being made by Robert Marsh and others, to determine whether it is suitable for steam-shovel work or the present caving system. Churn-drills are at work on the deposit. The overburden is about 2.7 cu. yd. per ton of ore. The mine contains about 8,000,000 tons of 2.5% ore.

NEW MEXICO

Grant County

The Chino Copper Co.'s mill has four units at work for five days per week, and producing about 50% of normal output. The Company reports as follows for the second quarter of 1914:

Overburden moved, cubic yards (9 shovels working)	1,119,805
Cost of stripping, cents per yard	30.7
Ore treated, tons	587,900
Average copper content, per cent	2.165
Recovery, per cent	66.897
Concentrate produced, tons (16.276% copper)	52,323
Copper production, pounds	17,032,871
Total profit	$1,102,104
Dividends paid	652,080
Surplus	450,024

SOUTH DAKOTA

Lawrence County

A committee from the U. S. Industrial Commission, consisting of R. Commons, A. B. Garretson, John B. Lennan, and John O'Connell, have been at Lead investigating the relations existing between employers and employees at Lead, mainly concerning the Homestake Mining Co. A large number of witnesses were summoned, including Thomas J. Grier, superintendent of the Homestake. He supplied the authorities with records of the Company, and all information asked for was gladly produced. Never has so much data been given as to its operations as a gold producer, and one interested in the welfare of its employees. There are about 2200 men employed, receiving from $2.50 to $7 per day in wages, and a total of $225,000 per month. Bishop Busch, of the Roman Catholic church, who is said to have instigated this investigation, is to testify before the Commission.

A half car each of cyanide and sheet zinc, quantities of fluxes, acids, crucibles, and other assay and mill supplies were destroyed in a fire in the warehouse of the Kirk G. Phillips estate at Deadwood on the night of July 20. The total loss was placed at $20,000, of which only $1700 consisted of buildings. As this was the only stock of cyanide and zinc in the Black Hills, there was a threatened shortage of the former, but it is not expected that any of the mills will be forced to close, as a new shipment will be rushed to Deadwood and in the meanwhile the Homestake and other operators who keep some surplus on hand, will share with the less fortunate. It happened that a carload of zinc was on the way to Deadwood when the fire occurred, so there was no shortage of that commodity. A peculiar feature of the fire was that a quantity of asbestos mixture pipe covering was completely destroyed; not a trace of it remains.

TEXAS

El Paso County

The American Smelting & Refining Co., operating the El Paso smelter, will pay 10c. per pound for copper and 25c. per ounce for silver in ores from mines with which it has contracts. D. J. Roberts, ore buyer for the Company, when at Globe, Arizona, urged companies to curtail operations somewhat.

UTAH

Beaver County

A rush has set in for the gold district in the Bald hills, 15 miles north of Beaver. The area is the only unwatered portion of the eastern part of the county, while the people voted it 'dry' at last election. A correspondent to the *Nevada State Journal*, of Reno, talks of "intense excitement," "a second Goldfield is thought possible," "new town of Fortuna in the throes of birth," "golden gate to a golden avenue," "city of gleaming tents throws back the sunlight across Beaver valley," "men grim in the lust for gold," "all hearts afire," "old-timers from Nevada stand aghast," and so forth. It is sincerely hoped all this will turn out as dreamed.

Ore assaying 194.8 oz. silver and 58.8% lead, and 37 in. wide, has been cut in the Leonora mine in the Star district. Work done here 30 years ago missed this ore by four feet.

Juan County

The Chief Consolidated Mining Co.'s report for the first half of the year shows that development totaled 3353 ft. One shoot extends from the 750 to 1400-ft. levels. Ore is being opened also at 1600 ft. Another shoot is from 1250 to 1700 ft. depth, the latter level showing $35 ore for the last 100 ft. There was shipped 23,739 tons of ore assaying 0.198 oz. gold, 16.56 oz. silver, and 9.01% lead, a gross value of $16.46 per ton. The total metal content was 4689 oz. gold, 393,151 oz. silver, and 1,696,798 lb. lead. The net yield after paying transport, sampling, and smelting was $183,288, or $7.72 per ton. With cash on hand, etc., there was available $408,538. Of this, $125,777 was operating expense, and $42,838 in dividend. Cash on hand at July 1, 1914, was $228,135.

Salt Lake County

Smelters around Salt Lake City continue to buy ore, but are holding up payment until the metal market is settled. C. W. Whitley, general manager for the American Smelting & Refining Co., said that the smelters of the Company at Murray and Garfield would not be closed on account of the falling off of the demand for copper. He said that the future operation of the Garfield plant depends on whether the Utah Copper Co. ceases mining copper ore on account of the European war, and whether the plant at Murray continues to accept ores for reduction. The forces at the two plants will be maintained as they are at this time.

G. W. Heintz, manager for the United States Smelting, Mining & Refining Co., said the Company would not close its smelter at Midvale nor any of its mines which are producing copper, lead, or silver. He said the matter of closing the smelters which accept custom ores depends on the mining companies. Mr. Heintz attributed the deferring of payments on copper ore to the suspension of quotations on metals. He said that they might be suspended indefinitely.

The Salt Lake City Stock Exchange is still open, with big business and knocking down prices.

The Utah Copper Co. reports as follows for the second quarter of 1914:

Capping removed at mine, cubic yards	1,824,997
Ore treated, tons	2,006,157
Average copper content, per cent	1.4573
Recovery, per cent	68.44
Copper production, pounds	40,017,562
Net profit from milling operations	$2,424,536
Dividends from Nevada Consolidated, etc	394,569
Total profit	2,819,104
Dividends paid	1,201,710
Net surplus	1,617,394
Copper on hand and in transit, sold and unsold, lb.	46,704,098

The above figures are in every instance an advance over the previous term.

The Utah Copper Co.'s Arthur mill has been shut down in-

definitely, and the staff transferred to the Magna mill, where it is hoped to keep the men employed half time. Practically construction work at the Company's properties has been stopped.——The A. S. & R. plant at Garfield has now only three reverberatory furnaces working, and the men will work half time.

The Utah-Apex Mining Co.'s quarterly report shows gross receipts of $161,450; expenses, $105,308; development, $3664; interest, etc, $5488; and net profit, $46,988. The new mill is doing good work, and is treating up to 425 tons of ore per day. The residue disposal problem has been solved by buying 100 acres of land at low cost.

Summit County

A transmission line two miles long is being strung by the Utah Light & Power Co. from Park City to the Silver King Consolidated. This will require about 30 days. A change from steam to electric power is to be made.

CANADA

Alberta

There is still considerable activity in the Calgary oil district in spite of the war, as many of the companies were financed before it started. The Dingman well is producing 250 bbl. per day, selling at $1 per barrel, and retailing at 25c. per gallon for gasoline. The Monarch well is down 2100 ft., and oil is expected in 200 ft. The drilling record was 1600 ft. in three weeks. Geologists of the Canadian government are examining the district. Henry R. Johnson, of California, has 16 men examining the fields in the Northwest.

British Columbia

During the past week 22 mines of the Boundary and Kootenay districts sent 8887 tons of ore to the Trail smelter, making a total of 211,105 tons for the first seven months of 1914. The Whitewater and Panama mines in the Slocan and Ainsworth districts made initial shipments to Trail; also the Molly Gibson, near Nelson, resumed ore deliveries, the first since February.

Ontario

The uncertainty of the silver market has affected mines at Cobalt, and some are expected to shut down.——After a shutdown of about two years, underground work has been resumed in the Vipond mine near Porcupine. Dorr machinery is being installed in the mill.——In the North Thompson mine, adjacent to the Vipond, there is 16 ft. of ore at 200 ft., according to diamond-drilling. Other development is encouraging.

Quebec

At the last session of the provincial legislature the price of the mining land was reduced from $10 per acre, according to its distance from a railway line, to $5, irrespective of its location. The prices of $20 and $10 per acre as the price of mining concession were adopted in 1907. Although these rates were higher than in the provinces, this was counteracted by the fact that the system of mining licenses allowed liberal time, at a yearly rental, to search and develop, and the high prices for the concession did not need to be paid before the mineral deposit had been sufficiently proved.

Yukon

The Pueblo copper mine, near White Horse, is shipping 250 tons of ore per day to Skagway *en route* to Tacoma smelters. ——The proposed government wagon-road from Skagway to the summit of the White Pass has been surveyed, the work being done under L. T. Merry, with E. Achison and H. Olson, in about six weeks. The road is intended to connect at the international boundary line at the summit with the Canadian roads to Atlin and Yukon territory as far as Dawson. The average grade is under 5%, and at no point will it exceed 8%.——Thirty-seven licenses have been issued in the territory for motor vehicles, 26 being in Dawson.

PERSONAL

Thos. F. Ryan is at Paris.

Karl and Anton Eilers are in Germany.

R. S. Rainsford has accepted a position at Detroit, Michigan.

Barton Sewall, president of the Braden Copper Co., is in London.

F. L. Cole was in Korea in June, but has since returned to Shanghai.

Will L. Clark was in San Francisco on his way to Salt Lake City.

Elbert H. Gary, of the Steel Corporation, is among the Americans at Paris.

Ludwig Vogelstein, of L. Vogelstein & Co., when last heard from was in Rotterdam.

E. K. Soper is in northern Minnesota for the Minnesota State Geological Survey.

L. E. Belford and L. M. Lewis recently crossed the Nevada desert from Fallon to Reno.

H. Foster Bain is at Salt Lake City attending the annual meeting of the American Institute of Mining Engineers.

Lloyd B. Smith has returned to Pittsburgh, Pennsylvania, after seven months' geological work in the Oklahoma oilfields.

H. L. Smyth is to be head of the combined school of mines of Harvard University and Massachusetts Institute of Technology.

D. M. Riordan has been appointed to act as special adviser to the Secretary of the Treasury and has sailed on the *Tennessee* for Europe.

C. T. Griswold has returned to Pittsburgh, Pennsylvania, from Newfoundland, where he spent July examining copper mines and prospects around Notre Dame bay.

Arthur L. Walker, who has been visiting metallurgical plants in Michigan and Montana, sailed on July 9 from Vancouver for a holiday visit to Japan and China.

Weldon Morris, formerly superintendent of the Hornsilver Mining Co.'s property in the Hornsilver district, south of Goldfield, has been appointed superintendent for the Goldfield Oro Mining Co., which duties he assumed on August 1.

Stanly A. Easton, general manager for the Bunker Hill & Sullivan M. & C. Co., was reëlected president of the Caledonia Mining Co. at the annual stockholders meeting on August 4. C. Fred Kratzer, of Spokane, was reëlected vice-president; Charles McKinnis, of Wallace, Idaho, was reëlected secretary, treasurer, and general manager; and John A. Finch, of Spokane, and J. E. Gyde, of Wallace, were reëlected to complete the directorate.

Obituary

W. S. O'Brien, general foreman for the Homestake Mining Co., died at his home at Lead, South Dakota, on August 1. He had for sixteen years been in the employ of the Company in various capacities. Born in Maine 69 years ago, he served in the Civil War, later removed to Minneapolis, from where he went to Montana, and afterward followed mining in that State, Nevada, Idaho, Utah, and California. He was a member of the constitution convention which organized the state of South Dakota, was later a state senator, and afterward state mine inspector, which position he resigned to enter the employ of the Homestake company. His death was rather sudden, caused by a severe hemorrhage induced by miner's consumption, from which he had been a sufferer for several years. His family consisted of three daughters, two of whom are married. All of them reside at Lead.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, August 13.

Antimony	No quotes
Electrolytic copper	" "
Pig lead	3.90
Quicksilver (flask)	$85.00
Tin	No quotes
Spelter	" "
Zinc dust, 100-kg. zinc-lined cases	" "

The principal local dealer in these metals reports no prices at present. Supplies of zinc dust are low, but a consignment is expected on a steamer from Europe at any time if not intercepted by German warships. The zinc smelter at Canon City, Colorado, produces about 20 tons of dust per month, and the total consumption in the United States is about 85 tons per month. It is reported that the export of zinc from England and Europe has been prohibited, being necessary for war purposes.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, August 13.—There being no market for copper, there are no quotations available. Exports for the first week in August were 5056 tons, a decrease of 4343 tons. The A. S. & R. Co. has declared dividends of 1¾ and 1¼ on preferred and common stock respectively. Idle cars in the United States on August 1 were 198,998, against 228,381 two weeks ago. Lead and spelter are strong and advancing, good demand for domestic trade, and enquiries from England.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Aug. 6	No quotes	July 1	56.58
" 7	" "	" 8	56.42
" 8	" "	" 15	55.60
" 9 Sunday		" 22	54.14
" 10	" "	" 29	53.42
" 11	" "	Aug. 5	No quotes
" 12	" "	" 12	" "

Monthly averages.

	1913.	1914.		1913.	1914.

May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The silver market is practically at a standstill, the following being some transactions: Bullion worth $2,000,000 left Vera Cruz for London on August 7. The English government was buying the metal for coinage purposes, but on August 11 it was cabled that there had been a reaction in price to 26½d. (53c.) per ounce, as the currency requirements had been temporarily satisfied. The San Francisco Mint is buying 200,000 oz. at 51.5c. The U. S. government has also bought 1,175,000 oz. at 52c., delivered at Denver, Philadelphia, and San Francisco. The U. S. Assay Office at Salt Lake City is paying 51c. for silver taken in through the purchase of gold. As Cobalt, Ontario, mines can only get 25c. per ounce, the balance on future settlements, several of them are reported to be shutting down. The general position promises to be better.

COPPER

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16.54	14.21	July	14.21	13.26

June	14.71	13.60	Dec.	14.25	....

As will be seen by reference to 'The Mining Summary' of this issue, there has been a general reduction of output of copper, the great mines being at practically half capacity, which is necessary. The last quarterly reports of the 'porphyry' companies show large stocks of metal on hand and in transit. Imports of copper into Germany during the first half of 1914 were 116,904, of which 102,188 tons was from the United States. This business is entirely stopped. There have been sales in London at 12¾ to 13¼c., and also in New York at 12⅝ to 12¾ cents.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

The price of this metal is still moving up and stocks are low. The Nevada Cinnabar Co., operating near Ione, Nevada, has 165 flasks of mercury at Battle Mountain on the Southern Pacific railway, and which is on its way to San Francisco. Supplies from Europe are stopped indefinitely.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Joplin, Missouri, zinc people expect a rise in this metal, as Europe supplies 66% of the world's total, this being cut off for the present.

TIN

There is no local quotation for tin, while the latest price in New York was 65c. per pound, with further increases certain. The chief sources of this metal are Australia, Bolivia, and the Federated Malay States, shipments usually going direct to England or Holland, these routes now being interrupted by the war.

CYANIDE

Enquiries show that stocks in the United States are normal at the mines, but very low on the Pacific coast. A steamer has been expected at San Francisco with a cargo of this salt. Supplies mostly came from Germany, while the firm of Roessler & Hasslacher manufacture some in New Jersey. It is suggested that the cyanamide made at Niagara Falls be tried if supplies run out. A large tonnage of German cyanide is made from the residue of beet-sugar mills, and should be made in the United States. The process was described in the Mining and Scientific Press of August 2, 1913. The Rand, Australia, India, and other mining countries depend on Germany and Glasgow for their supplies.

METHODS OF OIL RECOVERY IN CALIFORNIA. By Ralph Arnold and V. R. Garfias. No. 70. Petroleum technology 16. P. 57. Ill., index. This paper discusses the general methods employed for recovering oil when, owing to insufficient gas pressure or other causes, it does not rise to the surface by natural flow.

BRASS-FURNACE PRACTICE IN THE UNITED STATES. By H. W. Gillett. No. 73. Mineral technology 14. P. 298. Ill., index. This bulletin is issued as a contribution to the increase of safety and efficiency in the preparation and utilization of the mineral resources of the United States. There are probably 3600 plants melting brass or bronze at work at the present time, which vary from one small furnace to great concerns melting up to 50,000,000 lb. of copper alloy per year. Alloys employed and their uses are legion, and castings vary from a fraction of an ounce to 10-ton propellers for ocean liners. Losses in melting average about 2.5%. In this work is discussed the types of furnaces used, furnace data, general factors affecting furnace operation, possible improvements to furnaces, fuels, and disease and danger to brassworkers.

COMPANY REPORTS

STRAITS TRADING COMPANY

This Company operates tin smelters at Singapore and Penang, practically controlling the business. During the six months ended March 31, 1914, the profit was $250,700. A dividend of 50c. and bonus of 25c. per share was paid; $66,000 was carried forward. Smelting capacity is to be enlarged.

WAIHI GRAND JUNCTION GOLD COMPANY, LTD.

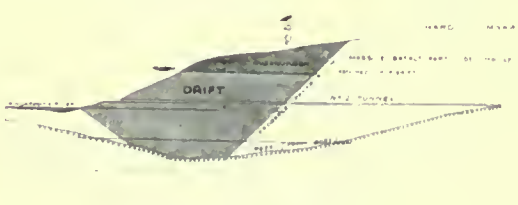
This Company's property is east of the Waihi mine, New Zealand, and lodes of the latter run into the Junction, which are the source of ore supply for the mill. The report under review covers the year ended December 31, 1913, and the remarks of the general manager, William Frank Grace; mine manager, William McConachie; mill superintendent, James R. Noble; and electrical engineer, W. H. Cole, are included in the following abstract:

Previous labor troubles retarded mine development, which totaled 5909 ft., against 8751 ft. in 1911, there being plenty points of attack had men been available. The cost of this work was $1.55 per ton. Work on No. 6 level on the Empire lode and Empire foot-wall leader was highly satisfactory, but the Royal lode east of the cross-cut was disappointing, although on the level above it was of good width and value. Little work was done on other lodes. The main shaft was sunk to 1212 ft., and No. 7 level is being opened at 1200 ft. Sinking was done in spite of 35,000 gal. of water per hour, and during the year a total of 106,936,610 gal. was pumped. (The Waihi mine pumps lifted 537,300,000 gal. in the same year.) Ore reserves in eight lodes total 175,100 tons, of which 65,000 and 46,400 tons are in the Empire and Royal lodes, respectively. Broken ore in shrinkage stopes amounted to 33,180 tons.

The 40 stamp mill, which is being increased by 20 more head, treated 98,383 tons of ore averaging $8.74 gold, and $1.24 silver per ton. The recovery of these metals was 89.9% and 74.1%. Actual recovery of bullion was £180,020, being just £127 in excess of assay extraction. Sand treated was 17,151 tons, and slime 81,232 tons. Costs of treatment were $1.71 per ton. Several alterations were made to the flowsheet. The maximum electric load was 1300 kilowatts.

Revenue of the Company for the year totaled £179,358, after deducting New Zealand government go'd duty and realization expenses of £7509. The profit was £41,591, and balance from 1912 was £19,616, making £61,207 available. Of this, £19,219 was paid as a dividend of 24c. per share.

ERRATUM.—On the 'Company Report' page of the *Press* of August 8 was the report of the Briseis Tin & General Mining Co., Ltd., illustrated by a line drawing which was similar in



CROSS-SECTION OF BRISEIS MINE, LOOKING DOWN THE LEAD.

some respects to the correct one as here used, but belonging to notes on the ancient gravel channels of Sierra county, California, appearing in 'The Mining Summary' of this issue. The Briseis tin mine is clearly shown in the accompanying cut.

New Machines and Devices

A New Electric Winch

The utility and economy of electric hoists has been so well established and their applications so numerous that a variety of special types has resulted. The electric winch shown in the accompanying illustration is one of the modifications of an electric hoist which has been designed for all kinds of hauling, usually in a horizontal direction and at comparatively slow speeds, one of the most frequent uses being for pulling cars. The pinch-bar method of moving cars is slow, and on curves or slight grades it sometimes fails entirely.

ELECTRIC WINCH.

The service of a switch engine is expensive, and the engine is not always available. For certain haulage problems the electric winch has been found to be particularly adapted.

The winch shown is self-contained and weather-proof in design and may be placed in a convenient position, and either by direct pull or with the aid of a snatch-block be made to move cars when and where desired. Other users are numerous and many will suggest themselves in the operation of mines and smelters. In the construction of this winch the aim has been to make it strong and simple. The entire mechanism is enclosed in the cast iron base to protect it from the elements. All parts must also be easily accessible for inspection. The motor is of the direct-current series wound or polyphase induction type and is geared to the winch head through a triple reduction gearing. The gears are steel castings and the pinions are steel forgings, all teeth being cut from the solid. The bearings are of bronze and are lubricated with grease by compression grease cups. The winch illustrated is one of the types manufactured by the Sprague Electric Works of the General Electric Co. with main offices in New York City.

Metallic Tape 'Threader'

The Lurkin Rule Co., Saginaw, Michigan, has just patented a measuring tape attachment known as a 'threader' which will hereafter be furnished with its metallic woven tapes. The 'threader' is a loop and stud arrangement by means of which the tape, though securely fastened to the winding drum of the case when in use, can yet be detached from it and a new tape attached, no manipulation of the case, case screw, or drum being required to do this. Woven tapes are sometimes torn or through use become worn in such a way that they must be replaced while the case is yet in fair condition. The case not receiving the same hard use as the tape-line, usually outwears it, and representing approximately half the value of the outfit, it is of importance that it be a simple matter for anyone to insert a new tape in the old case as often as necessary and thus get the fullest measure of use out of the case as well as the tape.

Commercial Paragraphs

SCHUTTE & KOERTING Co., Philadelphia, Pennsylvania, is distributing 'Catalog 8, Section H,' which is devoted to the hydraulic operating valve manufactured by this Company. This valve is designed for pressures up to 2000 lb. and is particularly adapted to hydraulic plants.

The NORDBERG MANUFACTURING Co., Milwaukee, Wisconsin, announces that it is now building high compression gas engines, especially in the larger sizes, having recently entered into a contract with the Usines Carels Freres, of Belgium, whereby the Nordberg company has been granted the exclusive privilege for the manufacture of this type of engine in the United States.

The JAMES ORE CONCENTRATOR Co., Newark, New Jersey, is supplying the new Butte-Timber concentrator with 8 tables which are riffled for heavy capacity to treat the re-ground and classified tailing product from the first set of tables. It is also proposed to treat the coarse portion of the flotation concentrates on a second set of 8 James sand tables to remove a lead product and a lead-iron middling product. The Company announces that it has a small laboratory at 35 Runyon street, Newark, New Jersey, for the accommodation of consulting engineers who desire to work out a flow-sheet for the treatment of complex or other concentrating ores, for the use of which only a nominal charge is made.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING Co., East Pittsburgh, Pennsylvania, has recently supplied the August Mining Co., of Landusky, Montana, with three 75-kva., 11,000-volt transformers, one lightning arrester, switchboard equipment, 12 motors of various sizes, and other equipment; the Anaconda Copper Mining Co. with four 30-hp. motors, three 3½-ton, 18-in. gage locomotives, making the fifth repeat order for this class of locomotive, and 10 motors for the new leaching plant being built at the Washoe smelter; the International Smelting & Refining Co. at Miami, Arizona, is being furnished with seven 50-hp. motors with magnetic brakes for operating 12-ft. Great Falls type converters, and 14 motors for other uses about the new copper smelter. The Westinghouse company is also supplying the Tooele smelter with 7 motors of various sizes to be used in the sintering plant at the old smelter, and a motor-generator set for use in connection with the Cottrell fume deposition process. Other orders which have recently been received include Ray Consolidated, sixteen 10-hp. special slow-speed motors for oil flotation plant; Utah Copper Co., seven 10-hp. motors for flotation plant; Daly West Mining Co., one 300-hp. hoist motor; Alaska Gastineau Mining Co., one 6-ton storage battery locomotive and one 50-kw. generator set; Empire Mines & Investment Co., one 500-hp. motor and liquid controller, three 200-kva. transformers, six 35-hp. stamp-mill motors and other equipment; Calumet & Arizona Mining Co., two 300-kva. transformers and switchboard equipment.

PETROLEUM producers are among those affected by the war, since petroleum and its products are largely exported, and in foreign ships. It is said that gasoline recently sold in London above Scotch whiskey.

MINING men interested in the Mother Lode and old neighbors and friends joined in giving a complimentary banquet to Mr. W. J. Loring at Calaveras Hotel, Angels Camp, California, Thursday evening. A fuller account will be given later.

ZINC-DUST is in large demand, as shown by our market pages. American zinc smelters have shown a general disinclination to go into this trade, mainly because of the trouble incident to maintaining a small side line, but now that the foreign supply is shut off at least two of the larger companies have undertaken to prepare dust for the cyaniders.

FLOTATION is attracting attention everywhere, but by reason largely of litigation, mine managers have been chary about giving out technical details for publication. Many, however, are glad to exchange information if it can be done anonymously. Our 'Concentrates' department has answered many inquiries already, and we will be glad to answer other questions regarding the technology of flotation so far as data are available and may properly be made public.

LEASING of coal lands in Alaska as a part of the conservation program upon which the Administration has entered, will soon be given a hearing before the House of Representatives. The present bill was drafted as the result of many conferences between the Secretary of the Interior, officials of the Geological Survey, and of the United States Bureau of Mines. The consensus of opinion regarding the measure is expressed by Mr. Lane, who has presented to Congress the urgency of Alaska's demand that these coal deposits be made available to the people for domestic purposes and the local industries. The bill if passed will permit of the leasing of large enough coal areas to warrant the installation of large equipment and permit of large scale operations by the payment of a reasonable royalty, while small areas may be mined without royalty to meet the domestic requirements. The bill contains provisos which make monopoly impossible and is generally conceded to be both fair and equitable. We would join the Secretary in his conclusion that the measure will provide a fair and acceptable method for the development of Alaska coal, will safeguard the interest of the public, and will result in direct and immediate benefit to the territory.

CALIFORNIA petroleum production for the first six months of 1914 is estimated at 52,411,390 barrels. Consumption is rated at 50,024,599 and the total stock of crude on hand July 1, at 52,145,007 barrels.

LITIGATION is notoriously expensive, but just how vexatious it may be in mining is illustrated by the experience of the Montana Mining Company, Limited. At the meeting when this Company's affairs were wound up, it was brought out that it took 28 years to get a final decision in the courts of the United States. In one case it cost $150,000 and six months time to get judgment for $905. It is not particularly surprising that Mr. R. T. Bayliss and his associates have turned to other countries for mining investments.

MINING men should take serious notice of a bill at Washington which passed the House last March and has recently been reported favorably to the Senate by the Committee on Education and Labor. It is House bill 10735 and it creates a new Bureau of Labor Safety, in the Department of Labor, with authority to investigate and report upon conditions of labor in all industries as regards safety. With the general purpose of the bill there is no disagreement, but it trenches severely upon the work of the United States Bureau of Mines, and in most undesirable fashion. There are few things that that Bureau has done better or with more general support than its work relating to safety in mines. The reason is that the work has been conducted by men familiar with mining as an industry and having at heart its good. The United States Steel Corporation has reduced its accident rate to little more than 25 per cent of the old rate without upsetting production, or seriously, if at all, increasing costs. There is a vast difference, however, between such work and a general stampede such as might readily result from the action of a labor bureau owing no particular allegiance to mining. This is undesirable and unnecessary. In the bill it is made the duty of the Public Health Service to furnish to the new bureau such reports on vocational diseases as may be needed, and in a similar way it would be easy to require that such investigations of safety in

mining as the new bureau requires should continue to be made by the Bureau of Mines. It is better to avoid trouble than to face it, and the Bureau of Mines should be allowed to continue the excellent work that it has already begun.

COAL PRODUCTION statistics as compiled by the United States Geological Survey during the past five years show a marked tendency toward large units of production in both the eastern and western coalfields. In the anthracite mines of Pennsylvania this tendency has been growing for many years and in the bituminous mines during the past five years there has been an increase in production of approximately one hundred million tons every year with practically no increase in the number of commercial mines. Mines of the first class, which produce over 200,000 tons annually, have increased 29 per cent in number and the average production of mines of this class has been raised from 300,000 to 350,000 tons annually during this period. The movement in coal as in metal mining is evidently toward wholesale operations with the reduction in cost per ton mined with the increase in tonnage.

ZINC is at present tending upward, and the rise in price is resulting in optimism on the part of the producers. The semi-annual production statistics of the United States Geological Survey printed on another page show the total domestic production of spelter from all sources to have been 175,058 tons during the last half year, as compared with 166,463 tons for the previous six months. American production has hardly met the home consumption, and it is anticipated that the increased demands of foreign markets formerly met by the German and Belgian smelters will bring a strengthening influence to bear upon the American spelter situation. Last week ore buyers throughout the West received orders to pick up all the ore they could find. The two important producers of spelter other than the United States are Germany, with an output of 298,794 tons in 1912, of which 49,895 tons was exported, and Belgium, with an output of 220,678 tons in 1912, of which only 73,964 tons was consumed at home, the remainder, 146,714 tons being sold in the markets of the world. Thus, according to the last Survey figures available, there would be a deficit of almost 200,000 tons of spelter in other markets of the world due to the suspension of Belgian and German furnaces if consumption remains normal. While a good percentage of the German and Belgian exports was consumed by Great Britain, there still remains a decided shortage to be met and American producers will hope to share in the spelter demand of neutral powers, provided that the spelter from our furnaces can be delivered to these markets. The spelter stock on hand in the United States on June 1, 1914, was 64,039 tons as compared with 21,856 tons at the same time of the previous year. The past year has not been a year of normal activity in the zinc industry, and we trust that the ill wind which is sweeping Europe will reduce spelter stocks and bring relief to smelters. This influence is already beginning to be felt. In the London, Joplin, and Platteville letters this week, our correspondents give glimpses of zinc mining in widely varied quarters.

MANGANESE is one of the minerals brought into demand by the war. Shipments from Russia have been discontinued, and even if trade routes be opened promptly it is hardly likely that men would be available to mine and ship the ore. Manganese has been selling in New York recently at 17 cents per unit. Since the war began, quotations of 30 cents have failed to scare customers. There are numerous deposits throughout the United States and preparations are being made to work many of them. The Carnegie Steel Company and the Illinois Steel Company are the only regular makers of ferro-manganese in the United States, though the Cambria Steel Company and the Tennessee Coal, Iron & Railroad Company formerly made it. The Tennessee company is reported to have made a small amount early this year, and the American Manganese Company owns two stacks at Dunbar, Pennsylvania, with ore lands in the Lake Superior region. This Company is reported to have on hand 50,000 tons of ore analyzing 10 to 20 per cent manganese and presumably will work this up. The Spanish American Iron Company formerly mined manganese ores in Cuba, but the works were burned during the revolution and have never been rebuilt. It would require about four months to get them into shape to resume shipments, but as consumers are said to be offering $75 to $100 per ton for prompt shipment of ferro-manganese, rebuilding may prove worth while.

DEVELOPING FOREIGN TRADE

The interruption of shipping in foreign bottoms by the war in Europe has roused American exporters to a keen interest in methods of stimulating the foreign trade of the United States. Numerous proposals have been made, some of them promising, others ridiculous. The most important of all the moves so far made is the action of the National City Bank of New York in making arrangements to act as a clearing house for South American credits and debits. For various reasons, one of them a law which until recently prevented our national banks from having any foreign branches, the American doing business in South America has perforce been obliged to carry on his banking operations through German and British banks. These international relations have become so firmly established that American banks hesitated to enter the field even after they were permitted to do so. The effect of the absence of any such relations is well shown in the case of the Guggenheim interests in Chile, which when their regular banking operations were interrupted by the war were forced to make arrangements directly with the Chilean government whereby the latter is to issue currency to the Guggenheim companies in Chile, against which the companies will make deposits to the credit of the Chilean government in New York.

Absurd as it may seem, it is actually the case that an American company doing business in South America has no means of financing its transactions there except through European banks. Seeking for foreign trade without providing banking facilities, is like going rabbit hunting without taking along a gun. After the tumult and the shouting of such proposals as that of employing our warships to carry contraband goods dies away, it is possible that the general agitation and discussion may have led to the carrying into effect of some of the more obvious changes necessary to develop our foreign trade. The tariff has been effectively revised downward, and presumably the guardians of the tariff wall are now not so potent as of yore in maintaining price levels in this country at the expense of the development of our export trade, and the few big shipbuilders who have maintained their business at the expense of our merchant marine are likely to be overrun in the sudden outburst of enthusiasm for the provision of American ships for carrying American goods.

THE TRADE COMMISSION AND MINING

The Senate has passed the bill providing for a Federal Trade Commission to exercise about the same authority over corporations engaged in interstate trade as is held by the Interstate Commerce Commission over the railroads. The act will doubtless become a law, and another great step toward government regulation of industry will have been taken. In general the country looks upon this with suspended judgment. Many are strongly favorable, others as strongly dissent, but the majority are probably disposed to see the new method of dealing with 'trusts' given fair trial. It is evident that much will depend upon the spirit and intelligence with which the law is enforced, since in many particulars its terms are broad. No one familiar with modern industrial conditions fails to recognize that they are in a most chaotic condition, but opinions differ as to whether this is due to too much or too little interference on the part of the Government. Certainly he is a wise manager who knows what he may and may not do and still stay within the law, and certainly there should be some simpler and more efficient method of learning than the old one of trial and error—especially when the latter invites prosecution, fines, and possible imprisonment.

Some forms of combination are necessary to the conduct of business and beneficial to both the country and the industry. This fact is tacitly admitted even when not stated in terms of law. We all rebel at discrimination, but there is more than fear of votes back of the exemption made in favor of combinations of laborers and farmers. The California fruit growers combination has been an efficient means of preventing waste and developing markets and, however much we may protest against individual acts of individual unions, we must all recognize that in the present stage of development they are necessary if workingmen are to have a fair chance. We believe that the country would be the gainer if it would recognize the fact that union in other lines is equally important and justifiable. In a straightforward and sound thinking address delivered before the Independent Producers' Association at Bakersfield a few weeks ago, Mr. Mark L. Requa pointed out that the Standard Oil Company has succeeded because it was an efficient business combination of producing, transporting, and marketing agencies, and that the independent could not hope to succeed unless he placed himself upon a similar basis. The advice was so taken to heart that a valuation of the independent properties is now being made with a view to possible organization of a single great company. We point out elsewhere that growth in the size of the unit is characteristic of business enterprises throughout the country, and to think of insisting upon a return to small warring units throughout the business world appears to us as absurd as to reëstablish in Europe the political conditions of medieval times. Whether intended or not, we believe the new Federal Trade Commission will be driven to recognize trade combinations and that it will find its chief usefulness in regulating them.

It is as illegal as it ever was for competing railroads to agree as to rates, but in fact freight and passenger rates are uniform, rate wars have disappeared, and the whole country is richer and better therefor. The laws of business have shown themselves superior to the laws of Congress, and we do not think it probable that the new commission will prove a drag upon industry. On the contrary, we expect to see it help and steady general trade just as the Interstate Commerce Commission has helped the railroad situation.

For many years the Interstate Commerce Commission had neither authority nor influence. It became the roosting place for 'lame ducks.' When, however, the law was amended, men of first-class ability were glad to serve upon it, and those already there became active. The result has been good for the country and the railroads. We expect to see even better results, as the commission learns that it may safely raise as well as lower rates. Good service and fair rates is what the American people want, but they sometimes need education as to what are fair rates. The success of the new commission will depend upon the men appointed, and we sincerely hope that among them may be at least one who is familiar with mining, one of the great basic industries too often overlooked at Washington. When it is remembered that even the 'granger' roads draw nearly one-third of their freight from the mines, and that to the railroads as a whole the mines furnish nearly 60 per cent of their freight, the importance of mining is better understood. The real value back of the securities of the United States Steel Corporation is the ore land owned, and many of the large railroad systems have more invested in mineral lands than in tracks. If interstate trade is to be intelligently regulated, the commission must have real knowledge of mines and mining, and that can best be insured by including among its members a mining man.

FIG. 1. GENERAL VIEW OF THE HILLSBORO PLANT OF

Zinc Smelting at Hillsboro, Illinois

By E. H. LESLIE

In passing from the natural gas zinc smelters of Oklahoma to the producer gas smelters of Illinois the transition is marked by a notable change in smelter equipment. While the underlying principles of zinc smelting are practically identical, the structural details, furnace practice, utilization of by-products, and stability of smelter design give to the Illinois smelters, and especially the more modern which will be discussed in this series, an atmosphere of industrial permanence and operating perfection which is not to be found in the natural-gas belt. The handling of supplies is more automatic; roasting furnaces of the single hearth reverberatory give place to multiple hearth muffle furnaces with sulphuric acid plants for the utilization of furnace gases; the cellar type distillation furnaces of Oklahoma are replaced by elevated floor furnaces in the more modern Illinois plants; waste heat boilers and regenerative equipment make for greater thermal efficiencies in the operation of the Illinois distillation furnaces; the storage and handling of fuel becomes a subject of importance and concrete and steel construction take precedence over wood and corrugated iron; power plants, machine shops, and accessory equipment are studied with greater detail and the industry becomes one which is dependent upon ore supplies and markets, and not upon a fuel which is abundant today and meagre tomorrow.

The American Zinc & Smelting Co.'s plant at Hillsboro, Illinois, is one of the most modern of American producer-gas zinc smelters. While the metallurgical process is almost identical with what has come to be recognized as standard practice in zinc smelting with producer gas and chamber acid process equipment, the layout of the plant and mechanical equipment for the handling of smelter supplies and the operation of the furnaces and various departments of the smelter, present many novel features which are interesting from a technical standpoint.

The smelter site is at Taylor Springs, about two and one-half miles south of Hillsboro, Illinois, and on the right of way of both the Chicago & Eastern Illinois, and the New York Central railroads. The property of the Company embraces about 200 acres of comparatively level ground, together with natural reservoirs for the storage of water and coal, and ample dumping ground to meet all the requirements of the smelter for years to come. A plan of the smelter buildings, standard-gage railroad sidings, and the reservoirs is as shown in Fig. 2.

BUILDINGS

The buildings are of structural steel and concrete with steel sidings and roofs which afford both permanent and fireproof construction. The character of the construction is seen from Fig. 1.

The fuel is supplied from the Illinois coalfield, which, with the modern coal storage facilities at the smelter property, guarantees a permanent and continuous fuel supply. The concentrates treated are derived largely from the mines of the American Zinc, Lead & Smelting Co., which are situated in the Joplin district of Missouri. Concentrates are also received from the Mascot property of the American Zinc Company of Tennessee with

THE AMERICAN ZINC, LEAD, AND SMELTING COMPANY.

other concentrates from Wisconsin, Colorado, and New Mexico.

The ore is received at the property in standard freight cars which are delivered inside of the ore storage house. As the cars enter the house they are run over a concrete waste-heat tunnel from the kilns seen under the freight cars in Fig. 3, and by this means the temperature of the ore-house is kept above freezing in the winter time. The concentrates, which are often frozen in the cars, are thawed in this manner and unloading facilitated.

The unloading of the cars is accomplished by an automatic scoop-shovel. The scoop removes the concentrate from the cars, after which it is elevated and discharged into a weighing hopper bin which is superimposed on a traveling gantry crane, which is seen in Fig. 3. This crane, with the elevator attachment, scoop-shovel, and weighing scales, which are mounted in it, is moved over tracks to convenient positions for unloading the freight cars. The traveling unloader and elevator are driven by a 25-hp. motor. The scales, with the hopper-bin attachment, are of 100-tons capacity, and the hopper-bin discharges into one-ton industrial cars by which the ore is distributed to the bins. There are ten storage bins with a total capacity of from 8000 to 10,000 tons. These bins are flat bottomed and made of concrete.

FIG. 3. WASTE-HEAT TUNNEL UNDER CARS AND UNLOADING CRANE.

STRAIGHT-LINE DRYERS

The concentrates are removed from the bins in buggies and wheeled by hand a short distance to the feed end of a duplicate straight-line dryer. Here the buggies are dumped into the boot of an elevator and elevated into a hopper-bin which automatically feeds the dryer. This dryer, which is 100 ft. long, with hearths 4 ft. wide, is heated by a dutch oven fire-box at the feed end of the furnace. The concentrate is drawn through the hearths by the rabbling mechanism, which consists of a continuous link belt arrangement, to which the rabbles are attached. When the rabbles emerge from the discharge end they are returned over the top of the dryer, and cooled on the return passage. The discharge from the dryer is screened, the oversize crushed in a pair of rolls, and the entire product elevated to overhead concentrate storage bins.

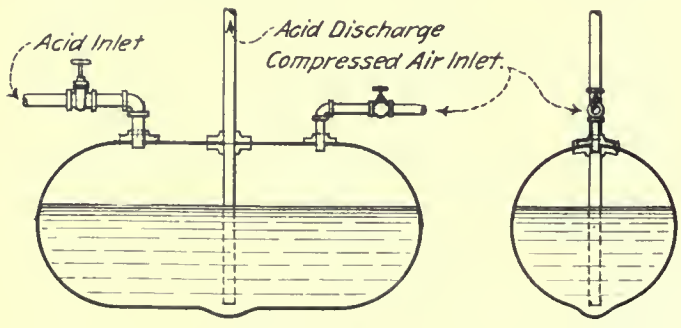

FIG. 4. AN ACID EGG.

The dried ore is drawn from the bins into industrial cars and trammed to the roaster house. Here the concentrate is dropped through a grating into the boot of a bucket-elevator, which elevates it to a spiral conveyor by which it is transferred to the feed hoppers of the roasting furnaces. The roasting equipment consists of two multi-hearth modified Hegeler furnaces, which consist of seven superimposed hearths 70 ft. long and 6 ft. wide. Each furnace is made up of two units of seven hearths each with two feed and two discharge openings. The ends of the hearths or muffles are inclosed by swinging sheet iron doors which are opened and closed by the passage of the rabbles. Each kiln is rabbled once every two hours, the rabbling requiring 15 minutes. The gas is burnt under the lower three hearths only, and the temperature of the hearths are recorded by a Bristol pyrometer, temperature readings being taken every hour. In this manner an accurate record of temperatures is kept and a uniformity in performance is possible. These furnaces are doing excellent work, reducing the 30% sulphur in the concentrate as fed into the furnace to 0.9% sulphur when discharged. The concentrate requires 72 hours in its passage through the furnace. Each batch as discharged is immediately sampled and the sulphur content determined. In this manner an accurate record is kept of the performance of the furnaces and any change in the condition is at once noted and corrected. The rabbling mechanism of the two kilns is of the regulation Hegeler type and driven by a 150-hp. motor. The gases from the kilns are conducted to the acid building through individual flumes and dust chambers. The fuel for the kilns is supplied by two Hegeler type gas-producers. The coal for the producers is unloaded from the cars by a locomotive crane and elevated to the hopper-bins which feed the producers.

The roasted concentrate from the furnaces is discharged into cars which are weighed and drawn through a tunnel and up an incline to the mixing room, where they are discharged into 12 steel and concrete storage bins. The roasting furnace building is being fitted with a vacuum cleaning arrangement by which all the dust about the furnaces can be collected and re-charged into the furnaces. On both sides of the furnaces there are chiseling tables supported on rails on which the furnace men stand when removing slag and clinkers from the hearths. The flue through which the furnace gases pass to the acid plant is lined with brick and the dust cham-

ber is fitted with baffles which assist in cooling the gases as well as separating the flue dust.

The acid building is a concrete and steel structure with steel roof and sidings. The building is about 325 ft. long by 100 ft. wide, with the working floor 6 ft. above the ground-level to permit of good ventilation. The acid process employed is the standard chamber process and the equipment consists of two Glover towers, a cooling and mixing tower, two systems of chambers of six each, and four Guy-Lussac towers, together with fans at the top of the Guy-Lussac towers and reserve fans at the end of the system. The gases enter the Glover towers from the kilns and from them pass to the mixing tower and then to the system of chambers. It is then returned to the Guy-Lussac towers, through which it passes in series and is finally expelled into the atmosphere. The weak acid from the chambers is returned to the top of the Glover towers where nitric acid is added to produce the nitrous oxides necessary in sulphuric acid manufacture and then passes through the three Guy-Lussac towers in series. The acid circulation is effected by means of acid eggs. The acid-egg pump consists of a steel shell about 7 ft. in length, 3 ft. in diameter, and elipsoidal in shape, as shown in the diagram, Fig. 4. The acid is admitted near one end of the egg and compressed air is admitted near the opposite end and on the upper side of the shell. The discharge pipe is connected at the centre and at the top of the shell and passes through to the bottom. When air is admitted the acid is forced out through the discharge pipe. This means of pumping acid has proved most effective in that it does away with the wear and tear on pistons and valves. There are no moving parts in the construction of this apparatus.

FIG. 5. HILLSBORO DISTILLATION FURNACE.

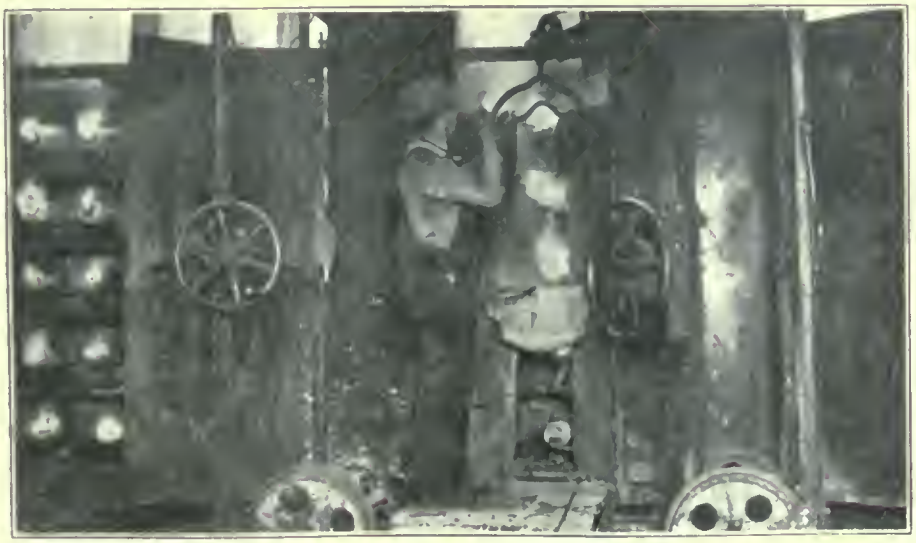

FIG. 6. DRAWING RETORTS.

About 1,250,000 lb. of lead has been used in the construction of the acid plant. Nitric acid used in the process is manufactured in a separate building on the grounds, the equipment consisting of an absorption tower and kettles. The sulphuric acid produced is 60 B. and is being manufactured at the rate of 200,000 lb. per day. The acid from the tanks in the building is pumped to tanks at the top of the acid building, from which it flows to three large 1000-ton steel storage tanks. From the storage tanks it is pumped by centrifugal pumps to the Company's tank cars, in which it is delivered to steel mills, fertilizer plants, glass factories, and other plants.

The roasted concentrate is drawn from the steel and concrete storage bins, which are about 1500-tons capacity, into a weighing hopper, where it is automatically weighed. The fuel is then added in the same hopper and contents are discharged into one of two drum concrete mixers. The discharge from the mixers is elevated by a bucket-conveyor, which dumps it into a car which holds one 'batch,' four 'batches' being required for a furnace. This car is pulled by a cable over elevated tracks to the front of the furnace. The cars are of the side-dump pattern and discharge through

FIG. 7. COAL STORAGE RESERVOIR AT HILLSBORO.

hoppers into the charging cars on the working floor of the distillation furnace building.

DISTILLATION FURNACES

The smelting department consists of five blocks of distillation furnaces, all under one roof. The building is of reinforced concrete with sides and roof of steel. The furnaces, Fig. 5, are 110 ft. long, with the working floor 16 ft. above the ground-level. There are 5 tiers of retorts and 20 retorts to a section, 20 sections on a side, thus making 400 retorts on a side or 800 to the block. The entire smelter comprises 4000 retorts.

The distillation furnaces are fired with producer gas which is generated in five gas-producer plants, which are of the Hegeler type as used in connection with the roasting kilns. The coal as received is unloaded from the cars by a locomotive crane and dumped into the boots of elevators and raised to the feed-bins which are superimposed over each producer. A drag mechanism is fitted to the bins whereby it is possible evenly to distribute the coal to the bins of the different producers. These producers gasify from 30 to 40 tons of coal daily. The gas enters at the end of the distillation furnaces and passes through toward the stack, air being added at each half-section to complete the combustion and maintain the high temperature of distillation. The air for the furnaces and gas-producers is supplied by duplicate fans which force it through concrete tunnels to the furnaces and producers. The fan-house is at the west end of the smelter building. Two of the furnace blocks are each equipped with two 264-hp. water-tube boilers. These boilers operate on waste gases from the furnaces and supply steam for power purposes. Another block is being equipped with two 400-hp. water-tube boilers, which when in operation will afford sufficient steam for all power purposes. The boilers are also fitted with Dutch oven attachments which can be fired in the event of a shortage of waste gases from the furnaces or to meet an increased load on the boilers. In this manner ample boiler plant is provided and excess furnace heat is used almost exclusively.

The retorts are charged by hand and are drawn three times a day. The drawing is done with the regulation draw car, as shown in Fig. 6, the metal being drawn from the condensers into a pot which is suspended in the frame of the draw car and brought into position under the condensers by means of a hand winch. The blue powder is re-charged in the last section of the furnace and the spelter is cast into slabs for shipment. The retorts and condensers are made in the pottery on the ground. The retorts are cleaned by means of steam which is formed by injecting water under pressure into them by means of a hose. Any slag or clinker which adheres to the interior of the retorts is removed by scrapers. When blowing out the retorts the operator is protected by means of a sheet iron shield which is suspended from a trolley rail in front of the furnaces. The life of the retorts is from 40 to 50 days at this plant.

The carbonate ore, which is mixed with roasted sulphide in smelting operations, is crushed in a special department for this purpose. It is first passed through a Blake crusher and screened through a two-mesh screen. The oversize is returned to a set of rolls for re-crushing and the entire product is then elevated and taken to the ore bins by means of a long belt-conveyor. These ore bins are of concrete and are situated over the tunnel from the roasting house. In this way the ore is dried sufficiently before being taken to the mixing room.

FURNACE BUILDING

In the design of the furnace building no effort has been spared to provide for the safety and comfort of the employees. The elevated floor structure permits of excellent ventilation and in addition to this, at con-

venient intervals in front of the furnace blocks there have been placed blower funnels connected with an air main and fan. By this means during the hot days of summer the furnace men by standing under these funnels are able to get relief from the intense heat which would otherwise be experienced. A refrigerating system has also been installed whereby ice water is available through sanitary drinking fountains throughout the plant. Change rooms with lockers for the men's use and sanitary toilet rooms are also provided. An electric freight elevator has also been installed for the handling of furnace supplies.

The furnace residues as discharged at the front of the furnace, drop through chutes to suspended hoppers below the furnace floor of the smelter building. These hoppers extend the full length of the furnace blocks and are 'W' shaped. Industrial cars of one-ton capacity are moved by a steam donkey locomotive into position under these hoppers and the residues are drawn into the cars and removed to the dumping ground. The depressions in the present smelter site are now being filled with residues and later a large tract of ground to the southwest of the smelter will be used as a dumping ground.

The coal storage system at this plant is one of the novel features and insures the Company against labor troubles in the coalfields and guarantees a continuous fuel supply for all smelter purposes. The coal is mined in the immediate vicinity of Hillsboro and brought to the smelter in the ordinary freight and gondola cars. That for immediate use is dumped directly into the hoppers which are adjacent to the producer plants or unloaded by a locomotive crane, previously described, into the storage-bins above the gas-producers. In order to assure a permanent fuel supply the Company has adopted a system of under-water storage and for this purpose has dammed up a natural ravine at the south end of the smelter site as shown in the plan. This ground covers an area of 4½ acres and by means of the dam a storage depth of about 30 ft. is available. The coal cars are run out on an 80-ft. steel girder bridge and dumped in that portion of the reservoir adjacent to the pumping station, as shown in Fig. 7. This coal is sucked up by means of a centrifugal pump and distributed through pipe-lines to whatever part of the reservoir is desired. These pipe-lines are supported on floating trusses, as seen in the illustration. In removing coal from the reservoir it is pumped out, lifted into cars and transported to the smelter. Twenty thousand tons of coal is at present stored in this manner. Besides being a convenient method for coal storage, the under-water system has been proved to be the most economic method,

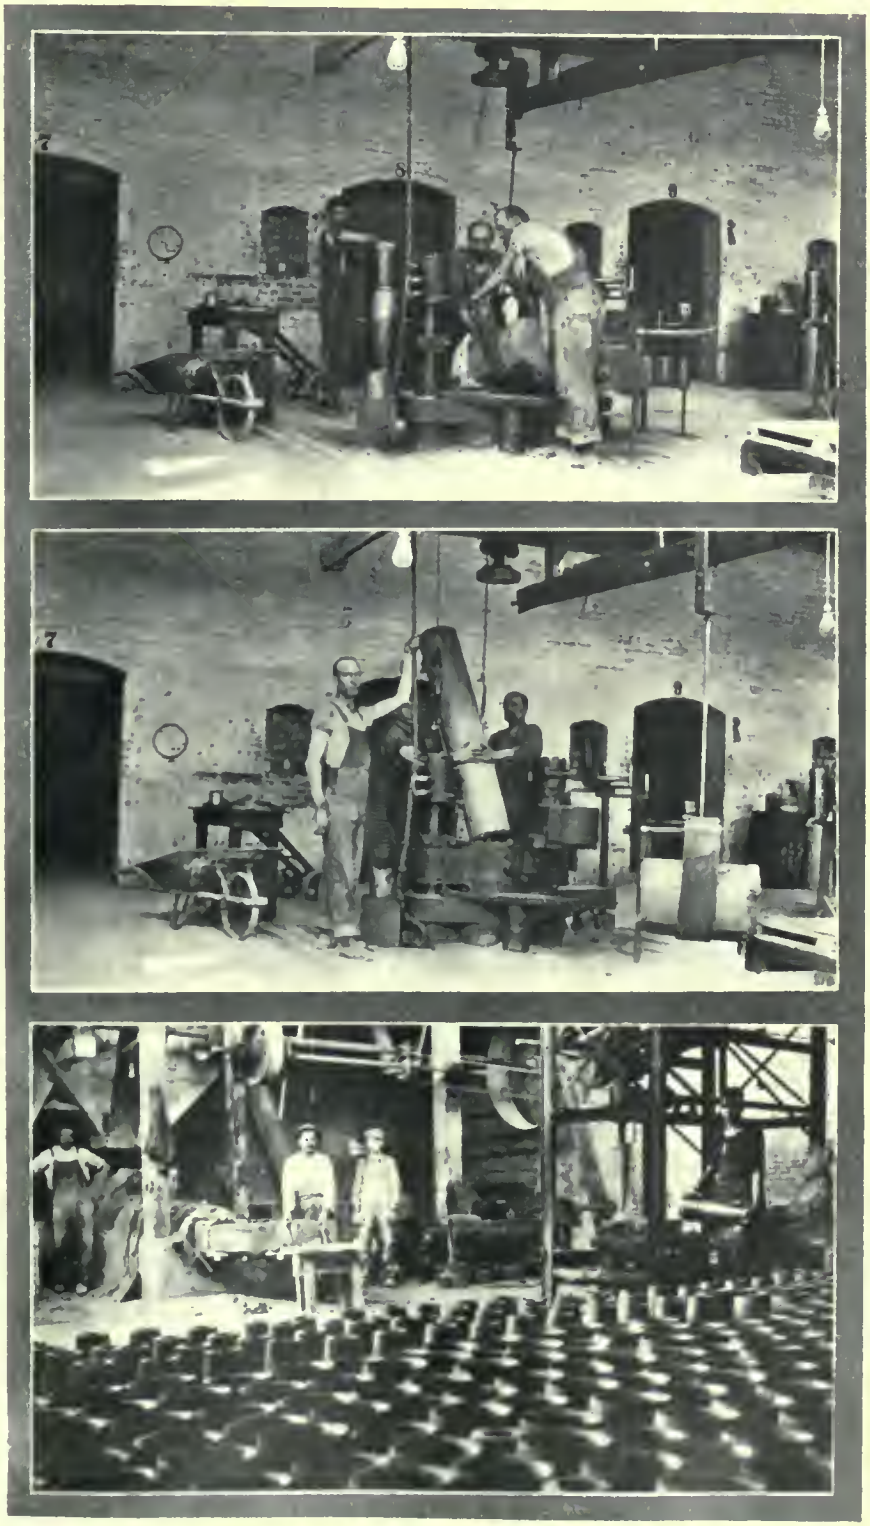

FIG. 8. MAKING RETORTS AND CONDENSERS.

in that the loss due to oxidation in weathering is reduced to practically nothing.

Pottery

The pottery plant, in which are manufactured retorts and condensers for the Company's use, is complete in every detail. The clay is delivered at the pottery over standard-gage track and stored out of doors, where it is allowed to weather from six months to one year. Missouri and Illinois clay is used for all pottery purposes. The clay stored inside of the pottery is only sufficient to meet immediate demands. The preliminary crushing of the clay and adobe is done in a Blake crusher and the material elevated to a screen, the oversize being returned to a pair of rolls and the entire product elevated to concrete storage bins. These bins have a capacity of 3000 tons, and the material from them is drawn directly into the pottery plant and fed into the first pug mill. Kilns have also been built for calcining clay and a separate set of rolls have been installed for the crushing of this material, which is also elevated to a separate compartment of the pottery storage bins. The calcined clay and green clay are given a preliminary pugging and then stored in cellars where it is allowed to 'rot' for from three to six months. The clay is then removed from the cellars and given a second pugging, after which it is taken direct to the retort press, Fig. 8. An additional pugging machine is about to be added to the pottery equipment. A hydraulic press of heavy design is used for the manufacture of retorts. The accumulator pressure at which this press operates is from 2000 to 2500 lb. per square inch. The capacity of the machine is about 400 retorts per day. From the press the retorts are taken to the dry rooms, of which there are 15 with a storage capacity of 1100 retorts each. These dry rooms are heated by exhaust steam coils in the floor and are kept at a temperature of 100 to 125° Fahrenheit.

The condensers are made from a mixture of clay and old retorts, the material being pugged and condensers molded in an auger machine. This machine, seen in the lower illustration of Fig. 8, has a capacity of about 4000 condensers per day. The condensers are taken from the machine, crimped, and dried in a special drying-room which has a capacity of 20,000 condensers. The retorts and condensers are taken from the drying-rooms, which are sealed by steel doors, loaded on flat cars, and hauled by an incline chain hoist to the furnace-floor, where they are tempered in down-drafts kilns. There are four of these kilns for annealing the retorts and burning the condensers. This same incline hoist is used for lowering the spelter from the furnace-floor to the loading platform. When the cars reach the platform they pass over metal weighing scales and a record is thus kept of the production.

The steam for all power purposes, as previously stated, is supplied by waste-heat boilers placed in the furnace flues. The engine-room equipment consists of two compound engines which are direct-connected to two, 400-kw., alternating current generators. These have both motor and turbo exciters. Power for the pottery is furnished by a 250-hp. Corliss engine. There are also included two small compound air-compressors which are used to supply air for air tools, lifting the kiln doors, and pumping acid. Duplex pumps are used for fire and service purposes. The water-supply is obtained from two natural reservoirs to the west of the smelter buildings, as shown in the plan.

The refrigerating plant is equipped with an engine and compressor, together with the necessary tanks and coils. Distilled water for drinking purposes is condensed from live steam in the power-plant. This water is aerated, filtered, and pumped to all departments of the plant, where it is available through sanitary drinking cups. The water from the two lake reservoirs is pumped into the service line by a direct-connected, motor-driven, centrifugal pump.

The laboratory building is of pressed brick and is equipped with all the necessary analytical apparatus for smelter use. There is also a small research department of the laboratory. The foundations for the balances in the balance-room are distinct from the building, and equipment throughout is the most modern. The machine plant equipment includes two radial drill-presses, one 30-in. lathe, a shaper, a pipe-cutting machine, a power punch, and shear, together with air tools and other minor equipment. There are also an electrical repair shop, blacksmith, and structural shops.

Power Transmission

All of the power is transmitted from the power-plant through concrete conduits to all departments of the smelter. About two miles of industrial track for the handling of smelter supplies and products is within the smelter grounds. Two saddle-tank locomotives and two 15-ton locomotive cranes are included in the equipment. An automatic call system has also been installed whereby the foremen may be summoned to the telephones which are at convenient points about the works, and in this manner it is possible for the head office to get in communication with any of the foremen in a very few moments.

The American Zinc, Lead & Smelting Co. has aimed to embody all that is most modern and efficient in the construction of this plant, and toward this end has succeeded most admirably in the construction of a smelter which is representative of the most modern practice. No effort or money has been spared to make the operation of the smelter as nearly automatic as possible, and it is also a pleasure to record that the comfort and safety of the men has been given considerable attention. While the metallurgy of zinc is often considered as having been marking time for the past 20 years, a visit to the Hillsboro smelter would contradict this opinion. Although retort furnaces and high fuel costs may be looked upon as necessary evils, the advance in the mechanical operation of our modern producer-gas smelters, of which the Hillsboro plant is typical, has reflected in increased efficiency and lower costs, the goal of all industrials.

Development of Gold Milling in the Philippines

By C. M. EYE

Prior to the occupation of the Islands by Americans, in 1898, there appears to have been little systematic attempt to develop their gold resources. For time immemorial, beds of streams and outcrops of gold-bearing lodes had been worked by natives with some success, the gold finding its way into commercial channels through the trading posts and ports. There is evidence that considerable work in this line had been done by Chinese, both in ancient and modern times, but to all these workers, the use of quicksilver was apparently unknown; the recovery of gold being made by very fine grinding in stone mortars and panning in copper vessels and 'horns' made of bamboo.

It seems remarkable that the Spaniards, usually such assiduous seekers after mineral wealth, should have paid so little attention to the search for gold, during the long period of their possession of these islands. Perhaps it was the almost entire absence of silver, perhaps the lack of evidence of fabulous richness such as lured them on to conquest in Mexico and Peru; perhaps they thought the promised gain not worth the risks involved in subjugating wild tribes, for it is a fact that their possession of much of the interior was more nominal than real; whatever the reason, they paid little attention to this line of industry, and followed the more attractive pursuits of agriculture, commerce, and politics—especially politics.

The San Mauricio

Some fifteen years prior to the date of the American occupation, an English company constructed a mill on the San Mauricio property at Mambulao, Ambos Camarines, consisting of ten stamps, a crusher, amalgamating plates, and Frue vanners; but it does not appear that this plant operated for very long. About the same time, a small Huntington mill plant was erected on a neighboring property, the Tumbagua, to work the free-milling ore from a small but high-grade vein. At the time the Americans came, both of these plants had been idle for years, and had fallen into decay. In 1900, not a single mine or mill was working in the Islands.

In the army of invaders, especially in the volunteer forces, were many men from various mining centres of the West. These were naturally on the lookout for evidences of minerals, and when hostilities ceased many of them took their discharge at Manila and scattered to the hills to prospect. The first gold mill built under American rule was made in Manila and taken to Benguet by a man named Hartwell, from western Montana. It consisted of three stamps of 500 lb. each, working in a sheet-iron mortar, with a few feet of copper plate below. Crude as it was, Hartwell operated it successfully on a surface deposit near Baguio, until smallpox claimed him as a victim. The next mill erected in the Benguet district was placed on the Comote mine, in the Antimok district, by three prospectors. It also was of Manila manufacture, but was heavier and more substantial than the Hartwell mill, having three stamps of 850 lb. each, working in a cast-iron mortar, with a 2-ft. apron plate and about eight feet of table plates. This plant was operated intermittently but successfully for a number of years, working on the thoroughly oxidized outcrop of a calcite-manganese deposit, in which the gold was clean and free. Only the softer portion of the ore was mined, owing to absence of crushing facilities. This ran from $16 to $25 per ton, and paid well for working, a fair recovery being made on the plates. Later an attempt was made to work the sand in the tailing by leaching, but without much success, owing to the difficulty of leaching manganese oxide-bearing material and poor classification.

The Copper King

In 1905 another three-stamp mill, of much the same style but better constructed, was erected on the Copper King property near Baguio. In addition to the stamps and plates, a Gilpin county bumping-table, constructed on the ground, was used with some success to recover concentrate which was high in gold and copper. In the meantime, in the Aroroy district, Island of Masbate, several promising ore deposits had been discovered, and small mills built to treat the ore from them. On the Eastern (now known as the Syndicate), a light three-stamp prospecting mill was built, but ran a very short time. The ten-stamp mill of the Tengo mine had a very short period of operation before being closed down, and the ten-stamp mill of the Gold Bug had a similar experience. This mill had two Woodbury belt-concentrators in addition to stamps and plates, but the sulphide content of the ore was too low to allow of making a commercial product. The failure of the early mills in that district was primarily due to their inability to make a sufficiently good saving by amalgamation alone, and, secondarily, to their lack of capacity, the ores in no case being rich, though of sufficient grade to constitute profitable ore when worked on a proper scale by correct methods.

First Cyanide Plant

The first application of cyaniding to gold ore in the Islands was made at the Minnesota mine of the Benguet Consolidated Mining Co. at Antimok, Benguet, in 1906. The milling plant, which I erected and operated, consisted of the following equipment: A 7 by 10-in. Blake type rodded crusher; one battery of three Hendy, quadruple-discharge, individual mortar stamps, of 1050 lb. each; a 4-ft. apron plate, followed by a 12-ft. table plate, both of silver-plated copper. After amalgamation, the

tailing was elevated in belt and bucket elevator, discharging into an inverted pyramidal upward-current classifier, the underflow of which was carried to any one of four leaching tanks, each 25 ft. diameter by 5 ft. high. There were also the usual number of gold and sump tanks, to accommodate strong and weak solution, and zinc-boxes for precipitation on zinc shavings. The whole constituted a leaching plant of the simplest character. The plant was driven from a 4-ft., double nozzle, tangential water-wheel, under a hundred-foot head. As first operated, with battery screens corresponding to 24 mesh, the saving by amalgamation was about 30%, and of the gold in the sand about 60% was saved in a treatment cycle of from 18 to 21 days. At first, an attempt was made to use lime made from vein calcite obtained from the Comote mine, fed dry with the ore, but the formation of calcium sulphate on contact with the free acid of the ore caused much blinding of screens and building up on all exposed iron surfaces, that its use was discontinued. Caustic soda was substituted and used exclusively for several years. Later, when better and cheaper lime was obtainable, its use was resumed though not as addition of dry lime. It was carefully slaked in considerable quantity, run off into pits, and covered with sand, then added as needed in creamy form to the tops of the leaching charges, as well as to the slime charges, for settlement and for securing alkalinity. On the whole, the use of caustic soda was more satisfactory in the leaching work, the only trouble arising with it being the formation of much insoluble hydrate when an insufficient quantity was used to secure distinct alkalinity. These hydrates were fairly readily dissolved on the addition of an excess of caustic soda solution, however.

Early Difficulties

When the plant began operations, it developed that serious loss occurred in the slime run to waste, which often assayed higher than the ore did as it came to the mill. An attempt was made to impound the slime, but the heavy rainfall of the country and the nature of the site in a narrow, steep cañon rendered this unsuccessful. Therefore, as soon as possible, a slime treatment was provided by building a pair of tanks of native pine, 16 ft. diameter by 14 ft. high, furnished with mechanical stirring apparatus. This mechanism, built in Manila from designs that I furnished, consisted of a vertical shaft with four stirring arms extending down into the tank from a truss above. This truss carried two vertical bearings and one ball bearing, the two former keeping the shaft in a vertical line and the latter taking the weight. The whole ball bearing was in turn suspended from a chain block, by which it could be raised and lowered through six feet. The gear worked on the shaft by a feather in a long keyway as in the Dorr thickener mechanism, and was driven from a pinion from a line shaft over the gear. A worm drive would have been much better, but was not locally available. The distinctive feature of the whole thing was the utilization of standard material as far as possible, the ball bearing being made by using one-half of a standard flanged shaft coupling keyed in a reversed position at the upper end of the shaft, with a casting containing the ball-race placed in position below it before it was keyed in place. The other half of the coupling was keyed into place in normal position at the lower end of the shaft, a square sheet of half-inch steel 16 in. square bolted up under it, the arms of a three-inch standard pipe being bolted up under this in the lines passing through to corners by U bolts. The cast iron stirrers, each made in two pieces like a split collar, were bolted on the arms and kept from turning by pins engaging in holes bored in the pipes. These rigs proved efficient and were used as long as the plant lasted.

Slime Treatment

The slime treatment consisted in alternate filling of the tanks, the stream being allowed to flow into one until a settled charge was accumulated, a charge being treated meanwhile in the other. The settled charge, amounting to about 35 tons and containing about 40% solids, was freed of the supernatant water by decantation, solution pumped on from the weak-solution circuit of the sand plant, brought up to strength of 3 lb. per ton in cyanide and 0.1% protective alkali in terms of caustic soda, and agitation continued for 18 hours with a dilution of from 2½ to 3 of solution to 1 of solids. Then the stirrer was lifted and the charge allowed to settle, and decantation begun, following the settling as fast as possible. Three successive charges of weak solution were pumped on, stirred with the charge, and decanted off, and a final charge of water put on, decanted to the weak-solution sand circuit, and the charge then stirred with additional water and discharged.

The chief difficulty with this plant was its lack of capacity. In order to handle the material faster, a 12-ft. Ridgway filter was installed, the plan being to give the slime agitation and one decantation in the treatment tanks, then pump to a thickening-tank, and to give it a final treatment on the filter. Unfortunately, the filter plant never had a chance to operate, as the plant was destroyed just at the time the filter was ready. Experiments made soon after the plant started operations showed that the iron sulphide panned from the pulp leaving the plates ran about $150 per ton, while sulphide panned from treated sand charges ran about $35 per ton. Therefore, a Wilfley table was placed below the classifier to handle the sand before going to the tanks. This table made a product running well above $100 and also enabled the elimination of more slime from the sand. The concentrate was accumulated with a view of putting in a small treatment plant, but after the loss of the plant, was shipped to San Francisco. The loss of the plant occurred in October 1909 from a flood during a heavy typhoon. Everything was lost but the stamps, plates, and water-wheel, the elevator, and one leaching tank. The stamps and plates were used on oxidized material during 1910-11, but another flood

near the end of the latter year carried away the wheel and plates as well as portions of the steel pipe-line, leaving the crusher, bin, and stamps remaining: a forlorn-looking wreck. It has thus stood ever since, but there are hopes now of a new all-sliming plant being put on the property on a more protected site. It should be remarked that a second battery of three stamps was erected about a year after the plant started, and a third battery had been purchased and brought to the site when the catastrophe came.

The Bua Mill

A year or so after the beginning of operations at the Consolidated, a somewhat similar plant was built on the Bua property, just below on the same stream. It consisted of a 7 by 10 crusher, six stamps, apron and table, amalgamating plates, a classifier, and six leaching tanks (each 20 by 5 ft.), the usual solution and sump tanks, zinc-boxes, etc. The ore, drawn from a different vein system than that of the Consolidated, consisted of calcite with considerable carbonate and oxide of manganese, the gold occurring free on the cleavage planes of the crystals of calcite and rhodochrocite. With crushing to 24 mesh in the battery, a saving of about 35% was made by amalgamation, and of the gold in the sand about 70% was recovered by leaching. The period for a complete cycle was from 12 to 14 days. The slime, fortunately, was low in grade, running $2 or less with the ore averaging $7 or $8 per ton. This enabled the slime to be run to waste without a great loss. Another advantage lay in the fact that the ore was naturally alkaline, thus obviating the necessity for the use of lime. Double treatment was used later, the practice being to fill by Butters distributor, give a preliminary treatment with strong solution for a couple of days, then drain and shovel over the charge in the same tank, beginning with a segmental cut along one side, which was thrown up on the charge. Then the charge was turned over, by successive slices, leveled off, and given a second treatment, first with strong then with weak solution, and finally washed. This plant had a successful run of several years, under the careful management of Con. O'Shea, but was finally put out of commission by the floods that wrecked the Benguet Consolidated plant. It was driven by a 4-ft. Pelton wheel, under a head of something over a hundred feet.

In 1910 a small stamp-mill, with plates, was erected on the Major group of claims, in the Baguio district, and in the following year a leaching plant was added, but it was never successful, owing to a combination of adverse circumstances. The ore deposits, rather bunchy in character, were scattered over a large area, making it expensive to handle to the mill, and the ore did not yield easily to the treatment. Steam was used for power, and wood became expensive and scarce when the supply adjacent to the works was exhausted. The life of this enterprise was therefore short, as it was impossible to overcome all difficulties.

During the same period the Headwaters Mining Co. built a mill, on its property near Baguio, which consisted of a crusher and ten stamps of 1050 lb. each, in two batteries of five each, all in one frame, mounted on a concrete foundation block. These were followed by double cone classification for separation of sand, which was reground in an 8-ft. Hardinge pebble-mill to −100 mesh, reclassified, and the oversize returned to the mill. The whole product finally passed as slime to a conical bottom steel thickening tank, of 24-ft. diameter by 24-ft. depth, which removed the battery circuit solution. This was returned to a storage tank set above the batteries. The thickened pulp passed to a series of two Pachucas, and thence to a series of two conical bottom decantation tanks, and finally to a Ridgeway filter. This plant was put into commission in 1911 and was the first plant in the Islands to dispense with amalgamation and to crush in cyanide solution, using continuous treatment throughout. The results were good, but owing to financial difficulties which arose, the first period of operation was only for a few months. Later it was started again, and I understand had a successful period of operation, until shortage of ore compelled a final shut-down.

In 1909, purchasers of the Old San Mauricio mine, at Mambulao, erected a mill of 20 stamps, and concentrating plant, and operated a short time, but were compelled to shut down permanently for lack of pay-ore. This plant (power for which was furnished by a modern steam plant using *manglar* wood for fuel) was substantially built and well erected, and deserved a better fate.

Considerable work was done, covering a period of several years, on the Tumbagua mine in the same district, the old Huntington mill plant having been repaired and used. While the ore was of extremely high grade, the vein was so small and the ore so scarce that it never scored a success.

The Colorado Property

Early in 1910 I assumed charge of the Colorado mine, in the Aroroy district, Island of Masbate, having examined it for intending investors in June of the preceding year. I recommended a continuance of development work and outlined a line of work to be followed. Preparations were made for the erection of an all-sliming cyaniding plant of a hundred tons capacity per day, the showing of ore fully warranting such a plant. This plant was finished late in 1911 and put in operation, development work having been constantly carried on in the meantime. It consisted of a jig-back aerial tramway a thousand feet long from the mine loading bins (the tram having a drop of one foot in two), delivering at the mill head to a 9 by 15 Blake crusher, set on top of a mill bin of 200 tons capacity. This supplied 20 stamps of 1250 lb. each, set on concrete mortar blocks of the Goldfield type, ten stamps to each block. The battery screens were 8-mesh, and solution was used in crushing, in a ratio of six to one of ore.

The combined stream of pulp from all the batteries was carried to a Dorr duplex classifier, set so as to feed by gravity two tube-mills, 5½ by 16 ft., these being placed with the long dimension across the line of the mill, the head or feed ends toward the centre. The discharge was carried back to the foot of a bucket-elevator, lifting 24 ft., which delivered to the same duplex classifier. The overflow from this, containing no particles coarser than 100 mesh, flowed to a Dorr thickener, 27 by 14 ft. The overflow from this, consisting of five parts of solution for one part of ore crushed, flowed to a sump tank supplying a triplex pump, which returned it to a storage tank of 50,000 gal. capacity set on the level of the base of the ore-bin. The thickened pulp, at one to one consistency, was drawn continuously to a series of two Pachucas, 40 by 15 ft., in the first of which it was diluted to about one and one-half to one, with strong solution brought up to requisite strength. After passing through the two Pachuca tanks, the pulp then flowed by gravity to another Dorr thickener of the same dimensions as the first, where a dilution of four or five to one took place, with barren solution from the extractor sumps. The overflowing solution, after clarification, passed through zinc-boxes, and thence to the strong-solution sump. The underflow of one-to-one mixture of pulp and solution went first by gravity to a mixing tank with mechanical agitator, and thence by gravity to two Oliver vacuum-filters, from which, after washing, it was discharged into a sluiceway leading to the river. The whole plant was thoroughly well constructed, all foundations and retaining walls being of concrete, and with floors of concrete on the tube-mill level, filter-floor level, clean-up room, and boiler-room. The mill was arranged in a series of eight descending benches or floors, terminating in the boiler floor on the level of the main roadway below. The material from the excavation, spread out on this level, made a splendid *patio* for storing the *manglar* wood, used in firing the three horizontal tubular boilers of 80 hp. each.

Changes in Operating Plan

The line of treatment given represents that followed at the start of operations. It was soon found that, owing to the extreme solubility of the gold, by far the greater portion was dissolved by the time it reached the first thickener. This necessitated making provision for precipitation at this stage of the treatment, which was done by moving three of the five extractor boxes to a level where the solution from the first thickener flowed through them by gravity and thence on by gravity by the Pachucas, furnishing the necessary diluting solution for the second thickener. The heads assayed about $12 per ton, and the solution from the first thickener from $1.60 to $2. After treatment in the Pachucas the second dilution and decantation left the solution of a value of about 40c. per ton, the overflowing portion of about five to one going to extractors, and the underflowing portion of one to one going with the pulp to the Oliver filters, where the washing reduced the value by somewhat less than half. All of the solution and wash from the Olivers went to the sump, and was returned to the solution circuit to the batteries. The principal defect in the working of the system arose from inability to secure sufficient wash on the filters without loading up the circuit with excess solution, the evaporation in that hot but humid climate being very slight. Since that time, the filtering plant has been rebuilt and two more thickeners added, as well as other minor improvements that have resulted in increased capacity and better saving.

Production

During 1912, with ore of about $12 grade and a saving of 90%, the production amounted to something over $330,000, of which practically one-half represented profits after all expense of development, mining, and milling were covered. While the report for 1913 is not yet at hand, the production was considerably greater, due to increased capacity and better saving. This was the first lode mine in the Islands to pay dividends, which it has done regularly since June 1912 at 10% semi-annually, besides accumulating a substantial sinking and improvement fund. It may be regarded as the first successful lode-mining venture in the Philippines. Plans have been prepared for the addition of ten more stamps and an additional tube-mill, to be placed this year.

The success of the Colorado has encouraged the owners of several other properties in the same district to equip with somewhat similar plants, though not so large. The Keystone erected and put a plant into operation last year, which consists of a crusher followed by two Lane slow-speed Chilean mills, and a series of Dorr thickeners without filters, the evident intention being to operate on the continuous decantation counter-current system. This plant has been in operation but a few months, and no data are available. Recent advices announce the beginning of operations in a similar plant on the Syndicate mine, above the Colorado. This is the old Eastern, mentioned previously, which, after the first fiasco, changed hands and was steadily though slowly developed, throughout a number of years. In it, as in all of the deposits of this district, the ore calls for fine grinding and cyaniding, amalgamation not being necessary, as there is no coarse gold present. The same is generally true throughout the Islands; certainly in the Aroroy and Benguet districts. The success of plants at the latter place will encourage resumption of milling in Benguet and elsewhere along the same or similar lines. It is said that the more wealthy Filipinos are now becoming interested in mining, since it has been demonstrated at the Colorado and elsewhere that it can be done profitably. Mining and milling are likely to always be minor industries there, but in view of what has already been accomplished, they are likely to contribute materially to the wealth and prosperity of the Islands.

Leaching Experiments on the Ajo Ores—III

By STUART CROASDALE

Sponge iron was first used as a precipitant for copper in England in 1837, although Gossage, in 1859, was the first to use it in connection with the wet extraction of copper from ores. It was made by heating a mixture of finely crushed iron ore and coal in a reverberatory furnace, with a reducing flame. Since then a great deal of sponge iron has been produced by iron manufacturers and a number of furnaces have been invented for its production, all of which are described in books on the metallurgy of iron and steel. It is now produced commercially at Hoganas, Sweden, by heating a mixture of fine magnetic iron concentrate and coal in pots or retorts by means of producer gas.

According to Sir I. Lowthian Bell,† oxide of iron is easily reduced by solid carbon, but carbon monoxide gas is greatly preferred as a reducing agent. The reduction of Fe_2O_3 begins at 420°F. The reduction of FeO begins at 1300°F. and is complete at 1475°F. Sponge iron readily combines with oxygen when exposed to the air at a red heat. It is also capable, at certain temperatures, of splitting up the carbon dioxide formed by its own reduction. The necessary reaction for the reduction of iron oxide by carbon monoxide seems to be

$$Fe_2O_3 + 9CO = 2Fe + 3CO_2 + 6CO$$

or, that there is as much oxygen in the CO escaping as in the CO_2 formed. This reaction is not so simple as it appears, however, for carbon monoxide gas is split into carbon dioxide and carbon in the presence of iron oxide or metallic iron, thus:

$$2CO = CO_2 + C$$

Hydrogen greatly assists in the reduction of iron oxide. George B. Frankforter, of the University of Minnesota, found that finely pulverized iron ore begins to reduce at about 300° F. in an atmosphere of hydrocarbon gas and is completely reduced below 1000°F. S. H. Stupakoff, in a paper read before the Engineering Society of Western Pennsylvania, states that carbon monoxide begins to reduce precipitated iron oxide at 285°F., roasted carbonate at 390°F., and is active on all ores at 750°F. It is most active at 1000°F. Solid carbon begins to reduce iron oxide at 800°F. The reverse action, of CO_2 being reduced to CO by metallic iron, begins at 800 to 1100° F., depending upon mass action, and is most active at 1475 F. A mixture of $3CO_2$ and 2CO is oxidizing at 1000 F., and a mixture of $1CO_2$ and 2CO is oxidizing anywhere above 1500°F.

My plan for the production of this precipitant was to manufacture sulphuric acid at the leaching plant, from the low-grade Bisbee pyrite, and then reduce the iron oxide in the calcine to sponge iron for precipitating the copper. The Bisbee pyrite contains about 38% iron and 1.5 to 2% copper. The copper would pay for the mining. The freight rate on this material from Bisbee to Ajo would be very low and divided equally between the acid and precipitating departments. The acid plant would be constructed so as to have the same life as the oxidized ore in the mine. In this way the cost of acid made at the leaching plant should compare favorably with that made at the smelting plant at Douglas, when the cost and maintenance of acid trains and storage equipment are considered in conjunction with the high freight rates on this commodity. The calcine from this pyrite would be in ideal condition for the production of sponge iron. It would contain a finely divided, porous, artificial oxide of iron which could easily be reduced at low temperatures. The product obtained from the reduction of the calcine would contain 60 to 65% metallic iron in a finely divided, porous condition that would present the greatest possible surface for the rapid precipitation of copper, and the copper contained in the original pyrite would all be recovered.

Laboratory Experiments

Laboratory experiments were made by mixing iron ore with 30 to 35% coal, both crushed to 16 mesh, and heating in a closed clay crucible in an assay muffle for 1 hour at a temperature of 1600 to 1800°F. From 75 to 77% of the iron in the ore was reduced to metallic iron. These experiments were repeated by mixing calcine with 25 to 30% coal and heating in the same manner; 98% of the available iron was metallized. Calcine was then placed in an iron tube and heated to a low red heat in an atmosphere of hydrocarbon gas for 1 hour. Over 90% of the available iron was metallized. This experiment was repeated and the tube was heated to incipient redness for 90 min.; 93% of the available iron was metallized. The gas used for heating the tube in this experiment was the impoverished gas coming from the reduction of the calcine. The available iron in these experiments was the iron existing as oxide and not that existing as sulphide.

These experiments were again repeated on calcine from Bisbee pyrite crushed to ¼-in. mesh instead of 16 mesh. At the end of 1 hr. 76.6% of the available iron was metallized and at the end of 2 hr. 88.3% was metallized. Sponge iron has been produced in quantity by iron manufacturers in small reverberatory furnaces, and, as I have stated, is now produced commercially in Sweden from magnetite concentrate in intermittent furnaces of the brick or pottery kiln type, so there is no doubt about the metallurgical condition necessary for its production, and the feasibility of its production for the precipitation of copper. The idea of using calcine as a source of iron is new, so far as I know, and was first proposed by me during the course of these experiments

†'Principles of the Manufacture of Iron and Steel.'

in the summer of 1912. The advantages of using this material are at once apparent from every viewpoint.

My efforts, therefore, were not to determine if sponge iron can be produced commercially, but to devise a furnace that will receive the calcine hot from the roasting furnaces, reduce it continuously, and deliver the metallized product or sponge iron to the precipitating department of the leaching plant. The problem is simply one of mechanical construction with no impossible or prohibitive features. The production of sponge iron is surprisingly easy, when the conditions are right.

After trying several small furnaces of different designs, I erected a Wedge double-function roasting furnace of special design to meet my conditions. This furnace was 9 ft. 9 in. diameter, had six roasting

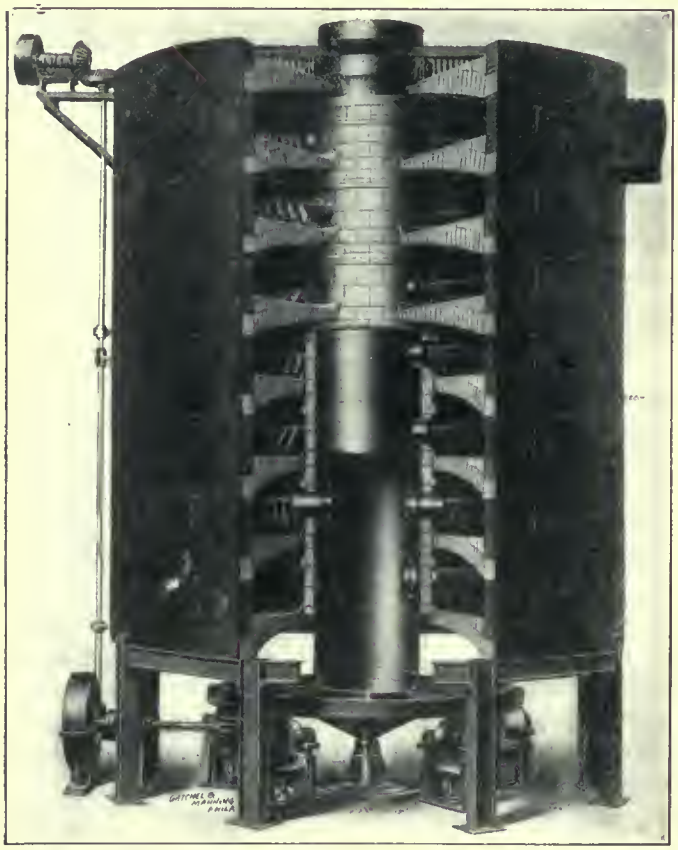

FIG. 2. WEDGE DOUBLE-FUNCTION ROASTING FURNACE.

hearths, one drying hearth, and one cooling hearth. The three upper hearths were of the ordinary type for roasting sulphide ore. The three lower were muffle hearths heated with oil from outside fire boxes. The two sets of hearths were sealed from each other by automatic cast iron valves. The entire furnace was sheathed with sheet iron except the top and bottom. Luting rings were placed around the centre shaft, and every effort was made to make the furnace as air-tight as possible. Each hearth was connected with the flue so the gases could be controlled as desired. A screw feeder was attached to the side of the furnace to deliver pulverized coal on the upper muffle hearth.

I expected to be able to roast Bisbee pyrite on the three upper hearths and deliver the red-hot calcine on the top muffle through the automatic valves, where they would be mixed with powdered coal from the feeder. In this way no heat would be lost and reduction would begin at once. I soon found that I had made a serious mistake in trying to put two furnaces into one, for I had neither a roasting nor a metallizing furnace. With all six hearths for either purpose, I would have obtained better results. The spaces for the passage of hot gases under the muffles were too small. In order to maintain the temperature that was desired on top of the muffle, the heat directly opposite the fire boxes was high enough to soften the clay tiles and cause them to warp. This allowed the calcine, already reduced to ferrous oxide, to drop into the joints and form a fusible slag which soon made a hole through the muffle and admitted air and products of combustion just where I wanted a reducing atmosphere. My greatest trouble probably came from air leakage through the bottom or cooling hearth and around the central shaft. The bottom hearth was made of brick arched in the usual manner. It was plastered on the under side with cement, but with the constant contraction and expansion of the furnace, it was impossible to make it air-tight. I would frequently get metallization well started on the middle muffle hearth and the iron would oxidize again before discharging. The luting rings around the central shaft, which were supposed to seal by dipping into the ore on the hearth, were not satisfactory for this purpose.

FURNACE TEMPERATURES

I endeavored to overcome these difficulties by producing a gas pressure inside the furnace from the combustion of coal. In this I was partly successful, and for short periods of time, until something broke or temperatures fell, I got encouraging results. The highest temperatures I was able to obtain on the muffles were as follows: top muffle, 1000°F.; second muffle, 1320°F.; third muffle, 1460°F.; cooling hearth, 1040°F.; but these were maintained only a short time before a muffle gave way. When reducing with coal, I should have had higher temperatures or at least 1400° on all the muffles. The soft coal used I thought had a tendency to deposit soot on the calcine at low temperatures, which retarded the reducing action. I tried lignite coal, but with so many other adverse conditions to contend with, I could not notice any difference. I also tried powdered coke, but at that time other conditions were unfavorable and the test was not completed. I was anxious to use producer gas, but had no opportunity to do so. My own laboratory experiments and those of all other investigators have proved that iron oxide can be reduced much more easily with gas than with solid carbon, and producer gas made from lignite or oil (which would be the cheapest fuels obtainable at Ajo) would contain the most active reducing agents known for this purpose.

I regret that my work in this direction was stopped before it was carried to a conclusion, but enough was

learned to satisfy myself that it will be entirely feasible to metallize calcine for copper precipitation at a cost of not over $5 per ton of metallic iron. Our estimated costs at Ajo were not much more than this, and they included half the cost of the pyrite. I believe a muffle type of furnace can be made practicable for metallizing calcine continuously, but it must be made gas-tight.

Pig Iron for Precipitation of Copper

When iron is mentioned for copper precipitation, no one in this country seems to consider anything but scrap iron as available for this purpose. It takes but a small amount of investigation, however, to find that pig iron is not prohibitive in cost at almost any point in the United States not remote from the railroad. It is reported that pig iron can be delivered on the Pacific Coast from China or India at a cost of $10 to $12 per ton.

The use of ordinary pig iron requires long launders and more or less handling of the iron to effect complete precipitation of the copper. Of course, the rapidity of precipitation depends upon the surface exposed, so I granulated the pig iron I used. This can be done best by shattering a small stream of molten iron with a jet of steam, and then cooling in a stream of water. The product was very hard and compact, and most of it was in the form of shot or pear-shaped drops. It contained 93.5% iron. A screen analysis gave the following results:

Mesh.	Individual, %.	Cumulative, %.
+ 4	2.0	100.0
+ 8	20.0	98.0
+16	31.0	78.0
+30	28.6	47.0
+60	12.4	18.4
—60	6.0	6.0

The relative precipitating values of the different sizes of this product were obtained by treating equal weights of each size with equal quantities of pure copper sulphate solution and also with lixivium obtained from leaching the oxidized ore. Each test covered the same period of time, at the same temperature, and was made under the same conditions:

Mesh.	Copper sulphate sol.:		Lixivium:	
	Grams Cu pptd.	Relative speed of pptn.	Grams Cu pptd.	Relative speed of pptn.
+ 4	0.050	1.0	0.06	1.0
+ 8	0.105	2.1	0.11	1.8
+16	0.385	7.7	...	...
+30	0.540	10.8	0.59	9.8
+60	0.925	18.5	1.05	17.5
—60	1.175	23.5	1.31	21.8

At the Gumeshevesky mine in Russia 12 tons of granulated iron is reported to have the same precipitating capacity as 120 tons of iron plates. The method of using granulated iron as a precipitant was also a small problem. Sponge iron from calcine or even from iron ore is attacked inside and out by the copper solutions, and each particle, large or small, is soon a mass of cement copper. Granulated iron is attacked only on the surface and unless agitated continually during precipitation it soon cements together into a solid mass which retards further action.

To overcome this difficulty, I made a tube-mill out of an iron pipe 10 ft. long and 20 in. diameter. It was fitted with 6-in. openings at each end for the admission and discharge of solution. It was filled to these openings with granulated iron and revolved at the rate of 12 r.p.m. The solution going into this tube-mill was a neutralized lixivium from leaching the oxidized ores. It contained

	Per cent.
Cu	1.64
Fe	0.34
Free acid	trace

It was passed through at different rates of speed to get the precipitating capacity of the mill. The results obtained from the solution passing out of the mill were as follows:

Rate, gal. per min.	4	6	7	10	12
Cu, per cent	none	none	none	0.06	0.09
Fe, per cent	....	....	1.98	1.88	1.84
Free acid, per cent	....	....	trace	trace	trace
Iron (100%) pounds consumed per pound of copper pptd.	....	....	1.00	0.97	0.97
Granulated iron, pounds consumed per pound of copper pptd.	....	....	1.07	1.04	1.04

The copper precipitate contained 73.6% copper. In a previous experiment, it contained 86.8% copper. By this method of precipitation the iron remained in the mill, always bright and clean, while the precipitated copper passed out with the neutral solution, from which it settled rapidly and could be removed by decantation. The operation is continuous. As seen by these results, the consumption of iron need not exceed 1 lb. for each pound of copper precipitated, provided the solutions are neutralized before precipitation. In a large plant these mills should be made longer and of less diameter than an ordinary tube-mill. The shell should be made of copper and lined with silex, to prevent abrasion. The galvanic current set up by the copper and iron would hasten the precipitation.

Electrolytic Precipitation

As usual, before starting a series of experiments, I compiled all the data available on this subject. These were obtained not only from published works, but from private notes and correspondence. The vital factors governing this method of precipitation are cost of power, material for anodes, and interference of other metals. The power required for deposition from clean copper sulphate solutions is about eight or ten times that re-

quired for refining purposes, or about 1 kw. per pound of copper deposited. The most economical current density is between 10 and 11 amperes per square foot, and the voltage required is about 2 volts, although with magnetite anodes it is said a current density of 15 amperes can be used. With an average cost of electric power of not more than 1c. per kilowatt the power costs for this method of precipitation need not be prohibitive. The anode material heretofore has been confined to lead or antimonial lead. Fused magnetite is now being tried and is said to be very satisfactory, although fragile and expensive. Its merits are yet to be demonstrated on a large scale. Lead anodes are gradually consumed, forming the peroxide of lead, which can be collected, reduced, and used over again if necessary.

Interference of other metals has proved the chief stumbling-block in most of the attempts to use the electrolytic method for the recovery of copper. Arsenic and antimony are troublesome, but are seldom found in appreciable quantities in leachable ores. Iron is the principal source of trouble, and with it may be considered manganese if present, for its influence is substantially the same as iron. Iron, by its alternate oxidation and reduction, consumes electrical energy without the deposition of copper. It must, therefore, be rendered innocuous by one of the following methods: Removal by precipitation, the use of diaphragms, or the use of depolarizers. Removal by precipitation on a large scale may be discarded at once as impracticable, for any effort in this direction would enable one to precipitate the copper direct by means of the same amount of chemical reagents and at about the same expense. The use of diaphragms has been tried repeatedly, but never successfully, on long-continued, large-scale operations. Under the conditions involved, it is improbable that they can ever be made to operate successfully, for diaphragm material that does the work required also increases the electrical resistance beyond commercial limits.

The use of a depolarizer seems to offer a way out of this difficulty. The most feasible depolarizer and perhaps the only one sufficiently cheap for this purpose, is sulphur dioxide. This has some advantages and some serious disadvantages. Theoretically, sulphur dioxide used in this manner will regenerate 3 lb. of acid for each pound of copper deposited. In experimental practice, 2 lb. has been the maximum obtained, owing to difficulties of manipulation. A certain amount of electromotive force is also generated in the direction of the current used, which reduces power consumption. These advantages, however, are more apparent than real. If much iron and alumina pass into solution from the ore, the actual acid regenerated in the electrolytic cells is relatively too small to be of any importance. On these Ajo ores, granting the best possible regeneration of acid from electrolytic cells, I estimated that 75% of the acid used will have to be made in an acid plant. In actual practice it would no doubt exceed this amount.

The mechanical difficulties in making the copper lixiviums absorb sufficient SO_2 gas to produce the desired results have not been solved. Introduction of the gas into the electrolytic cells at the anode secures a very small absorption and renders the electrolytic plant uninhabitable for human beings. Acid makers of experience do not offer much hope of success for absorption of this gas by means of scrubbing towers. Those who have tried to make SO_2 act as a depolarizer on a commercial scale report these claims a fallacy. Moreover, it has been found that when electrolytes containing SO_2 are used the current density must be reduced to the neighborhood of 3 amperes per square foot in order to get a satisfactory deposition of the copper. This means an electrolytic plant installation three times the size ordinarily required.

It has been found impracticable to deposit copper from electrolytes containing less than 1% copper. The average lixivium including enough wash water and acid to maintain a standard electrolyte will average between 1.5 and 2% copper. Assuming, then, for the sake of argument, that 35 to 50% of the copper can be deposited in good form by electrolysis (35% is actually the case in the only plant in operation), if relatively large quantities of iron and alumina pass into solution at each cycle of the lixiviant it will be necessary to discard the entire lixiviant in a short time or a portion of it at each cycle, in which the copper will have to be precipitated by a chemical reagent. This discarded lixivium will either be strongly acid or, if neutralized by fresh ore, will carry its full quota of copper. In any leaching operation, there will be also a gradual accumulation of wash water or weak solutions, which will have to be treated with a chemical precipitant.

The conditions governing the successful deposition of copper from solution by electrolysis have been determined quite conclusively after long and careful experiment by men skilled in the art. With ores that will yield lixiviums free from interfering elements, this method will no doubt prove a commercial success in spite of its expensive installation, but with ores like these where the iron passes into solution as readily as the copper, when the raw ore is leached with acid, it is almost a mathematical certainty that electrolytic precipitation cannot be made a commercial success and further experiment along this line is useless. A much more feasible method of overcoming this difficulty with iron would be to keep it from going into solution in the first place. This might be done by roasting the ore after crushing to the size required for leaching. The expense would be small. While there might be some danger of forming insoluble ferrites of copper, the iron and alumina would be rendered relatively insoluble in acid, the ore would be made more porous for leaching, there would be no argillaceous slime to absorb valuable constituents, the copper sulphides and cuprite would be rendered soluble, and the lixiviums might be clean enough for electrolysis. My work was finished before this was tried.

Phototopography

By J. A. MacDONALD

Topographic surveying, including phototopography, is the operation of determining and mapping the horizontal and vertical geographical features of the earth's surface.

Briefly, phototopography consists of photographing the country from prominent points and then plotting the data so obtained in the office. From this it is evident that it is only suited to rugged, irregular country, such that the various features may be easily recognized in the photographs. For these reasons it has reached its highest development in mountainous countries—

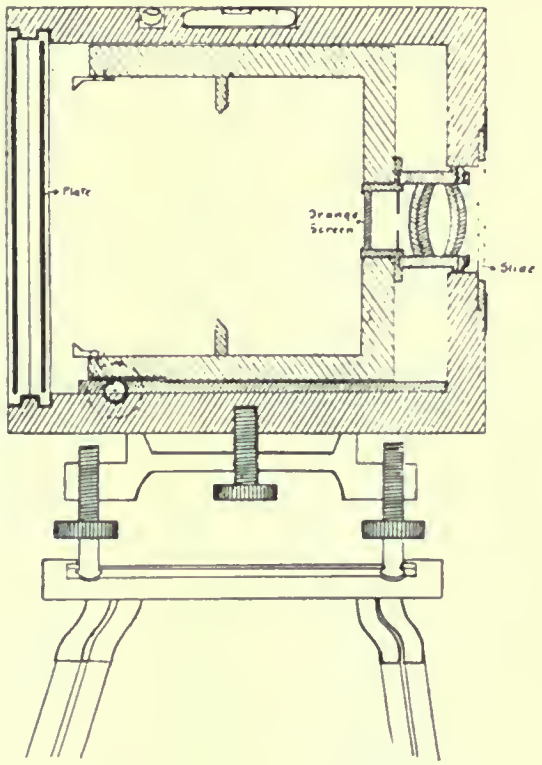

FIG. 1. THE DEVILLE CAMERA.

France, Italy, Switzerland, Germany, and Canada—and in no country has this method received such an extensive and practical application as in Canada.

In 1888, under the superintendence of our present Surveyor-General, Capt. E. Deville, who is an authority on this subject, an extensive photographic survey was commenced in the Rocky Mountains, in the vicinity of the Canadian Pacific railway, which was conducted with great success.

Encouraged by these results, the Department next employed it, in 1893, in making a topographic reconnaissance for the delineation of the Canada-Alaska boundary in southeastern Alaska; and since then, no other method has been used for that work.

The two instruments used are the camera and the transit. These instruments, in view of the fact that they are usually carried up steep mountain sides, and are often used under severe climatic conditions, in a very limited space of time, are necessarily of the simplest possible design. The standard Canadian camera, designed by Captain Deville, consists of an outer box made of mahogany inside of which is a second box, as shown in Fig. 1. The lens is attached to the inner box, which can be moved forward and backward by means of a milled screw projecting from the outer box, but which may be sprung in flush with the side when not

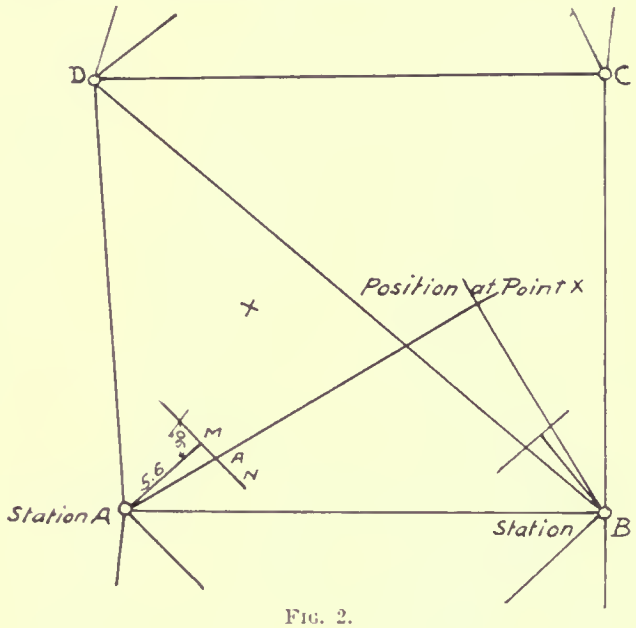

FIG. 2.

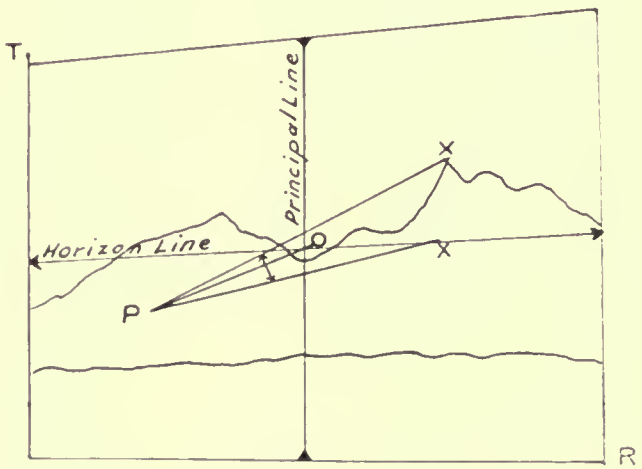

FIG. 3.

in use. The plate-holder fits into the larger box. When in use, the inner box is moved back so as to come in contact with the plate-holder (that end of the inner box, of course, being open), and the camera, having a constant focal length, is ready for exposure. The lens is a Zeiss Anastigmatic No. 3, of Series V, with a focal length of 141 mm. or about 5.5 inches.

An orange glass screen is placed behind the lens to fill the purpose of what in photography is termed a "ray filter."

A photographic survey is carried on, necessarily, in conjunction with a triangulation scheme, by means of which the positions of the camera stations are determined. The triangulation stations are so chosen that

they satisfactorily fill the function of such, and at the same time make good camera stations. The qualifications for this latter purpose are:

1. That they shall command a good view of the surrounding country, unobstructed by any close or higher peaks.

2. That photographs taken from these stations shall contain points seen from other stations.

3. That the angles of intersection at any points to be plotted from two camera stations shall not be too acute.

The judicious selection of stations requires a thorough understanding of the methods of plotting and also of the practical difficulties encountered in the field.

The signals used on the peaks for triangulation points are made of sheet iron, in 2-ft. lengths, fitting together like a stovepipe, and standing about 10 or 12 ft. high when complete.

Contour maps are made by showing 250-ft. contours. The number of points plotted to the square mile depends on the accuracy required, the topography of the space between the points being sketched in from the photographs.

Plotting Field Results

The method of plotting from the photographs is as simple as the field work. Fig. 2 indicates the principle of this method. The first operation in the office is to draw the horizon and principal lines on the prints. The horizon line is drawn so that all points having a greater elevation than the camera station will show above this line, while all points of equal or less elevation will show on or below it. The principal line is drawn vertically through points in the centre of the field of the camera. These lines are determined by joining the two sets of V-shaped projecting points which result from projecting teeth in the interior of the camera, near the plate, and carefully adjusted for that purpose.

After these lines have been drawn, the triangulation scheme is put on paper. In Fig. 2, assume that we wish to plot the topography between stations *A*, *B*, and *C*, which are three stations of the triangulation. Through *A* draw the line *AM* in the direction of that bearing, cutting off *AM* equal to 5.5 inches—the focal length of the camera—and at *M* draw *MN* at right angles to *AM*. Now, we wish to plot the position of point *X* indicated. Measure off, with dividers, the distance on the print of this point to the right of the principal line, and transfer it to *MN* such that *Ma* shall equal it. Through *Aa* draw a line and produce it. The position of the point *X* will lie along this line. Repeat the operation for the point from station *B*, and the intersection of the two lines so obtained will give the position of *X*. Similarly for all other points.

The elevations of the points are now required. In Fig. 3, where *TR* represents a photograph, and *OP* the focal length of the camera, it can be seen that the angle *XPX'* represents the angle of elevation of the point *X* from the camera. Now the horizontal distance of the point *X* may be scaled off from the plan. Knowing the angle of elevation, and the horizontal distance, it is a simple matter to calculate the elevation above or below the camera station, whose elevation is already known. This illustrates the principle of the method of determining elevations. In practice, however, a scale of heights' is constructed on this principle, by means of which the elevations may be determined graphically in a much shorter time.

Sulphur Deposits of Southwestern Texas

By CLYDE M. BECKER

What is probably the greatest surface deposit of sulphur in the United States, lies in southwestern Texas, chiefly in Culberson and Reeves counties. The sulphur occurs in a disseminated condition in the heavy gypsum deposits of that region. The zone covers several hundred square miles.

The gypsum in the valley from Toyale north to the Delaware hills, a distance of perhaps 75 miles, contains sulphur, which apparently was taken into solution and not deposited until the sea went dry. But where the sulphur is in sufficient quantities for commercial consideration, it is found in a single stratum or deposit which has the appearance of having been thrown down immediately upon the injection of the sulphurous spring waters into the sea water already saturated with gypsum. The latter is intermingled with the sulphur in these deposits, the sulphur content ranging from 20 to 30 per cent.

During the past 15 years these deposits have attracted considerable attention, but no really serious effort has ever been made to put them upon a commercial basis. Some years ago, however, a company said to have been composed of Italians, attempted to refine sulphur at Maverick Springs and on the Cooksy ranch, at a point seven miles north of Rustler Springs. From appearances, operations ceased very suddenly. The retorts at Maverick Springs are still filled with a partly refined charge, and most of the equipment is still on the ground. From this abandoned plant, it is apparent that these embryonic developers had little conception of the work in hand. They attempted to refine sulphur in steel retorts in a country where there is no water fit for boiler use within a radius of 20 miles.

The question of tonnage does not enter into this proposition. The problem is to work a great number of deposits from 15 to 50 miles from railroad transportation in a desert land where no good water exists. While the fact has not been definitely proved, it is probable that there is no single deposit of sufficient tonnage to supply a large plant any great length of time. To be a success the deposits must be worked on the 'steam-shovel basis.' It will take a man of steam-shovel proportions to do the job.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Rand Banket

Reply by Mr. Horwood to Waldemar Lindgren's Discussion

I thank Mr. Lindgren for his kindly remarks and for his criticisms on my work.

I agree that detrital gold, and also traces of the platinum metals of detrital origin, would occur in these conglomerates. I stated in my paper[1] that there may be a small proportion of pyrite and gold of detrital origin in the banket, but that, in considering the genesis of the pyrite and gold, the amount was admittedly unimportant; and I said that the same remarks applied with regard to the metals of the platinum group.

With regard to his reference to waters charged with hydrogen sulphide, I would like to record that I have occasionally detected the smell of this gas in connection with water issuing under pressure from the West Reef dike in the lower levels of some of the Randfontein mines.

Mr. Lindgren points out that the whole series must have been so porous that hot magmatic waters would necessarily have permeated the whole. I particularly mentioned that traces of gold could be found throughout the series, but gave detailed reasons why the gold was mainly confined to the conglomerates, and laid stress on the importance of the retaining influence of the underlying shales. I showed that the bankets were more easily permeable than the quartzites and so formed the main channels of circulation for the mineralizers, and T. A. Rickard emphasized this same point in his discussion on my paper.

Mr. Lindgren is mistaken in thinking there is an absence of fissures: surely, the dikes have been injected into fissures, also the numerous fault planes mark lines of fissuring. The longitudinal dikes are usually accompanied by reversed faulting, the rule being that the banket is up-thrown on the side of the dike that is farther from the lode outcrop. Throughout the Rand there is abundant evidence of fracturing and fissuring.

Reply by Mr. Horwood to Kirby Thomas' Discussion and to H. Foster Bain's Discussion

I greatly appreciate Mr. Thomas' kindly remarks on my series of articles on the Rand banket.

I was much interested in the analogy which he draws between the Rand deposits and the silver veins of the Cobalt district of Ontario, the latter occurring mainly in a Huronion conglomerate and in the Keewatin metamorphic rocks, their origin having been attributed by the Canadian geologists to the direct influence of a diabase sill; also, in the further analogy with the gold-bearing veins, in the conglomerate of the Kirkland Lake district of Ontario, which are apparently related to neighboring dikes and masses of syenite. Mr. Thomas further points out that the copper in the conglomerate of the Calumet & Hecla mine in Michigan has its origin in the associated eruptive flows similar to allied deposits in the amygdaloidal flows of the same district.

With regard to his suggested theory of the genesis of the lead and zinc deposits of Missouri, northern Arkansas, and Wisconsin, this has been fully combated and discussed by Mr. Bain in the *Mining and Scientific Press* of February 14. I take this opportunity of tendering my thanks to Mr. Bain for his kind reference, in the final paragraph of his discussion, to my work on the Rand bankets.

Reply to F. H. Hatch's Discussion

I have read the two criticisms on my paper, dated London, November 21, 1913, and January 12, 1914, by Mr. Hatch.

In the first, with which I will now deal, he states that on main principles he agrees with me, but differs in some minor matters. He agrees with me that certain ellipsoidal pyrite pebbles, which are microcrystalline and entirely devoid of radiate structure, are pseudomorphs after quartz pebbles; and he admits that the pyrite which forms the pebbles that have radiate structure may be, in part, of metasomatic origin and have replaced a portion of the silica of the groundmass. He supposes that those showing radiate structure are ordinary concretions; and does not agree with me in regarding some of these as pseudomorphs after quartz pebbles. He says he does not understand my explanation of the radiate structure, which he contends is a property of the pyrite. However, no evidence is brought forward to substantiate any of his opinions. In my paper I showed that the metasomatic origin was indisputable, as the structure of the material replaced was frequently plainly discernible under the microscope; in many cases where quartz pebbles had been replaced, their original outlines and internal structure were readily revealed by the microscope. Moreover, Fig. 15, 16, and 17 showed pebbles actually in process of replacement by pyrite. My explanation of the radiate struc-

[1] In footnote 187.

ture was expressed as clearly and in as simple language as possible.

Mr. Hatch laboriously tries to show that the discovery of the metasomatic origin of the pyrite, and that it sometimes is pseudomorphous after quartz pebbles, is not entirely due to my researches; and concludes his remarks by referring to a short article written by himself in 1911 in which he tardily admitted that the pyrite of the banket is of metasomatic origin, and that both the pebbles and the cement of the banket are replaced by pyrite. Most people who read my paper will probably agree that I have tried to give full credit to others for the work done by them, as the very frequent references testify, and that I have in no way attempted to take credit to myself for work done by others.

In 1904, Mr. Hatch, conjointly with G. S. Corstorphine, wrote a short paper entitled 'The Petrography of the Witwatersrand Conglomerates, with Special Reference to the Origin of the Gold.' This was a very interesting little brochure in which the subsequent infiltration theory of the origin of the gold was upheld, but no attempt was made to explain how the process of subsequent mineralization had taken place. A few specimens and slides of banket had been examined, but beyond this there was no evidence of any research work; nor, as far as I am aware, has Mr. Hatch done any such work in relation to the ore deposits of the Rand.

He attempts to discount the fact that I was one of the first to call attention to the pseudomorphous origin of some of these pyrite pebbles by laying emphasis on the circumstance that I withdrew the paper in which I discussed this matter and which was read before the Geological Society of London on February 27, 1907. Unfortunately, I was in South Africa when this paper was read.[1] It dealt with an occurrence, at the Crown Reef mine, of pyrite pebbles that I had studied in great detail. In this paper I pointed out that, in July 1903, G. Denny called attention to the existence of calcite pebbles in the Main Reef conglomerate in the Meyer & Charlton mine; and that shortly after, in the same year, Julius Kuntz, in a brief article written for the Geological Society of South Africa, clearly showed that these pebbles were calcite pseudomorphs after what were originally quartz pebbles. Mr. Kuntz was careful to point out that they occurred near a break in the formation, which break was now partly filled with calcite, and from which a great amount of water was still flowing; also that these calcite pebbles diminished in number as distance from the break increased, and that as they gradually diminished in number and finally almost ceased to occur, pebbles could be found consisting of calcite and partly of quartz, the process of replacement becoming more and more incomplete the farther the distance from the break. I then described in detail a similar occurrence of pebbles of iron pyrite in close proximity to a diabase dike in the Crown Reef mine, and laid stress on the fact that they occurred immediately overlying an impervious band of shale, at the base of the Main Reef Leader conglomerate. The details of this occurrence as given by me in my treatise on the Rand banket[2] are from my paper that was read before the Geological Society of London in February 1907. Mr. Hatch criticized my paper adversely at the meeting when it was read; and as he was looked upon as an authority on Transvaal geology, he is doubtless aware of the reason why it was proposed that only an abstract should be published. Under the circumstances, I preferred to withdraw the paper entirely. I have in my possession the original typescript of that paper on which the date that it was received by the Society, namely, January 12, 1907, is marked, and each page bears the official stamp of the Geological Society of London.

In discussing the paper, Mr. Hatch stated that it did not contain any facts tending to show that any of the pyrite pebbles were pseudomorphs after quartz pebbles, nor was there any suggestion made as to how such a replacement might be supposed to have taken place; also, that the specimens exhibited contained examples of pyrite nodules with radiate structure which were evidently of concretionary origin. It may thus be as well to give the following verbatim quotation from the latter part of this paper:

"At the Crown Reef mine, pebbles of iron pyrites occur in close proximity to a dike, at the base of the Main Reef Leader conglomerate and immediately overlying a band of shale. The matrix of the Main Reef Leader is, here, very pyritic especially at its base. The dike is black in color, of a very basic character, is highly decomposed, and has developed (doubtless due to pressure) a shaly, fissile structure. The intrusion of the dike was accompanied by a normal faulting movement, which has thrown the reef up a distance of 76 ft. on the south side, so that the Main Reef series is, here, exactly opposite the South Reef series. At the bottom of the particular stope in which these pebbles occur, and at the contact of dike and reef, on the north side of the former, the dike is altered for a thickness of about three inches into a light bluish gray clay decomposition product. At, and for some twenty feet up from, the dike contact, the shale underlying the Main Reef Leader is changed into a yellow, brittle, flakey porcelainite; above this it gradually assumes its ordinary character.

"A few pebbles of pyrites occur at the immediate contact of dike and reef and for about ten feet up from the dike; above that they are then of frequent occurrence right up to the top of the stope.[3] This stope 4 B.W.E. (N.O.D.) is between the 600 and 700-ft. levels,

[1] I have a letter from L. L. Belinfante, the assistant secretary of the Geological Society, in which he informed me that the senior secretary read my paper practically *in extenso* at the meeting of the Society.

[2] Except those relating to the microscopic investigation, these having been worked out by me at a somewhat later date.

[3] They seem to be especially numerous about half way up the stope.

the latter being 630 ft. vertically below the surface. The length of the stope is about 130 ft., and it dips at an angle of about 38°. It is one of the richest portions of the mine. For the last nine months of 1905 it averaged 22.8 pennyweights over 21¼ inches of reef, or 12.4 pennyweights over a stoping width of 39 inches; and for the first six months of 1906 it averaged 20.0 pennyweights over 22.5 inches of reef, or 10.7 pennyweights over a stoping width of 42 inches. Almost the whole of the gold is contained in the narrow band of conglomerate in which the pyrite pebbles occur: for example, during the first six months of 1906 the Main Reef Leader averaged 41.6 pennyweights over 9.1 inches, while that portion of the Main Reef which was stoped only averaged 5.4 pennyweights over 13.4 inches, the two together thus averaging 20.0 pennyweights over 22.5 inches of reef. This band is known as the Main Reef Leader, and here averages between 9 and 10 inches in width. It is underlain by a thin but very persistent band of shale, which averages, in this stope, about 2.8 to 3.5 inches in thickness. Small stringers of quartz, running parallel to the bedding, occur here and there in this shale band, affording evidence of the action of mineralizing solutions. Immediately below this band is the bed of conglomerate known as the Main Reef which in this mine varies from about 10 to 15 ft. in thickness; except occasionally, in places, it contains only a little gold. In mining the overlying Main Reef Leader a portion of the Main Reef is also extracted, it being impossible to carry the stopes sufficiently narrow to deal only with the Main Reef Leader.

"Similar pyrite pebbles are also occasionally met with further away from the dike, on the western face of the stope, as also in the stope immediately below.

"The dike is here about 40 ft. wide, and passes through the lower end of the stope. It strikes approximately 16° north of east and south of west, is almost vertical, dipping about 88° north; can be traced throughout the mine, that is for a distance of about 3000 ft., and extends westward into the Langlaagte Estate mine. Its average width in the Crown Reef mine is about 35 feet.

"Today the quartzites and conglomerates of the Witwatersrand Beds form an almost impervious mass, owing to the action of dynamic metamorphism, and to the deposition of secondary silica, and to a less extent pyrite and other secondary products, in the interstices of the original sandstones and conglomerates. Pressure exerted in a north and south direction has bent and folded the beds into their present position. This was accompanied by considerable fracturing, and consequently dike intrusions; thus solutions, ascending through fractures and along lines of weakness produced by fracturing and the intrusion of these older dikes, would have encountered the beds in a sufficiently pervious condition to penetrate them. Presumably, in this particular case, the mineralizing solutions which deposited the iron disulphide, and probably some, if not all, of the gold, ascended along the line of fracture and weakness, produced by the intrusion of the dike and spread out laterally near the surface, choosing one or more of the conglomerates as offering the easiest channels. Combined with its lateral motion, it would also have had a downward component due to gravity. As previously mentioned, the Main Reef Leader here immediately overlies a band of shale. This is fine and close grained, and its lines of stratification are parallel to the dip of the conglomerates. It thus forms a layer which is almost impervious to solutions circulating above it. Thus it is an easy matter to conceive how such solutions would naturally have concentrated above this layer, and might have precipitated some of their contents along its junction with the overlying and more porous conglomerate, especially as here the rate of flow would be somewhat lessened owing to the fact that the downward component of motion would be checked. If this is actually what happened, one would expect to find the majority of the pyritic pebbles at the immediate contact of the conglomerate with the underlying shale, and if there were any above this, that they would be less in number; and, this is how they actually do occur, and, I have not found any pyrite pebbles below this shale band.

"The pebbles vary in size up to about one inch in length, they are mostly circular, but some are oval, and they are all well rounded.

"In cases where pebbles have been fractured, they sometimes show an internally radial fibrous structure, which of itself is sufficient evidence that they have been formed *in situ*.[4] Further, the fact that in some, the quartz of the original pebbles has not been entirely replaced,[5] and in others the pyrite may be seen entirely surrounding the quartz, and, so to speak, eating into it, so that if the pyrite were removed what were undoubtedly originally smooth water-worn pebbles would present irregular fretted and corroded surfaces, is convincing evidence that they are pseudomorphs by replacement of the quartz of which the majority of the pebbles of the conglomerates are composed."[6]

London, June 1. C. B. Horwood.

(To be Continued)

German Southwest Africa exported material worth $17,575,500 in 1913, against $9,758,750 in 1912. The value in 1913 was made up as follows: diamonds, $14,727,400; copper ore, $1,432,170; tin ore, $157,840; and marble, $7240.

---

[4]They do not all exhibit this radial structure, and those which do may be concretions, or it is quite possible that they are pseudomorphs and this structure has been developed later, owing to a gradual molecular rearrangement.

[5]In the specimens marked A, B, C, and D (these were exhibited at the meeting) there are pebbles consisting chiefly of pyrites but also partially of quartz and in which the outline of the original quartz pebbles are distinctly visible.

[6]They have, in fact, been produced by a process similar to that by which the original material of many ammonites and other fossils found in the chalk of the Cretaceous system in England has been gradually replaced by marcasite.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

ALL UNDERGROUND AIR MAINS in the Mt. Morgan mine, Queensland, may be supplied with water under high pressure for fire-fighting purposes. The scheme is quite satisfactory.

COAL 'shot off the solid,' that is, blasted by powder without being previously undercut or sheared, in Pennsylvania in 1913, was less than 3% of the total output of 265,306,139 tons.

BOILERS using waste heat from furnaces of any kind should be arranged for the gases to pass through in a straight line, and with plenty of passage area, in order not to affect the draft.

TO REMOVE 35,000,000 cu. yd. of sand in the harbor of Toronto, Ontario, the dredge *Cyclone* has been constructed to handle 15,000 cu. yd. per day. The boat is 170 ft. long and 42 ft. wide, and the pump is driven by a 1750-hp. engine.

THE WOODEN STAY between the orebin and king-post of a battery is generally held in position with long bolts. In some instances these are being replaced with angle plates at each end of the timber. A firmer joint is insured and less attention is needed.

DESERT SAND makes it almost impossible in some places to haul ore or supplies in mining districts. To overcome this a mining company in Riverside county, California, has laid two miles of 3 by 12-in. Oregon pine planks for truck or wagon wheels, the space between being left bare.

DIPPER-DREDGES *Chagres*, *Mindi*, and *Cardenas* at Panama during the first five months of 1914, working 8-hour shifts, moved 290,996, 247,502, and 273,826 cu. yd. of material respectively, being increases of 61.5, 106.3, and 9.2% on the average of the past three years. These boats cost about $100,000 each.

AMALGAMATION of silver ores is less successful than with gold ores. The reason for this is in part that the specific gravity of silver is only about half that of gold. Gold occurs almost entirely in the native state, whereas silver is generally found in combination, argentite, a sulphide, being the principal ore.

CLASSES OF ORES suited for zinc-retort smelting are straight zinc ores, products from the concentration and separation of zinc-lead ores, and products from the concentration and separation of mixed and complex ores containing gold, silver, lead, copper, and zinc. At the present time the lower limit of zinc in ores or mill products suited to this purpose is about 25 per cent.

A NEW METHOD for the determination of hydrocyanic acid and the alkali cyanide is described by G. E. F. Lundell and J. A. Bridgman in *The Journal of Industrial and Engineering Chemistry*. They summarize the process as follows: The new method consists in making the cyanide solution ammoniacal, then adding a small amount of methyl glyoxime solution and finally titrating this prepared solution with a standard nickel ammonium sulphate solution until a permanent red precipitate is produced. Results show that the new method is accurate, free from ordinary interferences, usable in cloudy solutions, rapid, cheap, and of value in titrations of double cyanides.

LOW-GRADE SILICIOUS FLUE-DUST is a nuisance to smelt in reverberatory furnaces, forming a blanket on the charge. At the Steptoe plant, Nevada, certain dust in the flue contained 3% copper, 23.41% silica, 4.08% iron, 2.72% lime and magnesium oxide, 6.07% aluminum oxide, 19.94% free sulphuric acid, 25.10% sulphur trioxide combined as sulphate, and 10.67% water with the sulphates. By adding water to this, enough acid was obtained to leach the silicious flue-dust. As it is drawn from the dust chambers it is sluiced to vats or dams and settled. The clear solution flows to a 10 by 40-ft. wooden tank which is filled to 7 ft. with carbonate ore capping from the mine. This is leached over night. The copper-bearing solution is then precipitated by scrap iron. The cost of the complete process is about 8c. per pound.

FABER DU FAUR TILTING FURNACES are largely used for the retorting of zinc 'crusts,' a process which leaves a silver-lead alloy for pouring. The operation of retorting is a lengthy one, and condensation of the zinc commences at a comparatively low temperature. This allows ample time for the furnace to attain full heat, so that the whole of the zinc is expelled. The furnace has been largely adopted in Western Australia for the melting of gold precipitate in cyanide plants, with very satisfactory results. Elsewhere a neglect of important considerations has invariably led to a condemnation of the furnace for this work. It is imperative that the design of the firebox should be so modified that sufficient heat is obtainable from the commencement. For this reason ample fuel space should be arranged, and the thickness of graphite at the bottom of the crucible should not be so excessive as it often is, when the apparatus is used for retorting zinc crusts.

Salt Lake Meeting of the Institute

STAFF REPORT

Despite wars and rumors of war, though there was temporarily no market for copper, and an uncertain one only for most other metals, the meeting of the American Institute of Mining Engineers at Salt Lake City last week was the most largely attended and in many particulars the equal, if not the superior in interest, of any other in the history of the Institute. The differences of opinion as to the conduct of the Institute which developed in 1911 have had the effect of stimu'ating interest in it to a degree that is ample compensation for the friction then generated. There are strong disagreements now as to what should be the policy of the Institute in many particulars, such for example as to participation as a body in efforts to secure revision of the mining law, but there is no disagreement as to the value and importance of the technical sessions. The Institute members are coming to take a keen interest in its affairs and to recognize that its value to them lies as much in the opportunity to meet the leaders and the coming leaders of the profession face to face, as in the receipt of printed papers. No one is able to become very enthusiastic over being one of several thousand patrons of a publishing house, but when you have dined with a man there is a new bond, and when in addition you have spent several days with him visiting mines and smelters and discussing technical problems, he has become more to you than a mere name. It is this purpose that the Institute is coming to serve in a greater and greater degree. One of the most pleasant features of the meeting was the large number of private dinners and luncheons given every day to small circles of friends renewing acquaintance. Alumni of the Massachusetts Institute of Mining Engineers entertained R. H. Richards on the roof garden at the University Club, Wednesday evening, while at the same time members of the Sigma Chi retold college tales at a table on the beautiful roof garden at Hotel Utah, the official headquarters. The dinner was attended by C. L. Berrian, W. W. Case, Jr., L. C. Lennox, W. E. Greenough, Raymond Guyer, E. Pembroke, James D. Mooney, Fred Scibird, F. Faulkner, and G. T. Hansen. At a neighboring table, while the sun set beyond the Great Salt Lake, W. L. Saunders, D. W. Brunton, W. L. Clark, C. W. Goodale, and H. Foster Bain recalled pleasant days in Japan with Jintaro Kojima of the Furukawa Copper Company. Mr. Kojima is mining engineer at the Ashio, the largest copper mine in Japan, and though a member of the Institute since 1906, this was his first opportunity to attend a meeting in the United States. Excepting Willard S. Morse and Seeley W. Mudd, the Americans present included the whole of the little party which was so lavishly and pleasantly entertained at Ashio in 1911. There were many other reunions and these are but examples.

There have always been those who appreciated the value of the organization as a means of extending acquaintance, but the possibilities in this direction are apparently just beginning to dawn on the membership at large. Some came in private cars, some in Pullmans, and others mayhap in the day coach, but all felt that it was an opportunity not to be missed, one worth some sacrifice, and that is what made the meeting a success—that and the hard intelligent work of the local committee, the directors, and the regular officers of the Institute.

The general program of the meeting and the list of papers presented has already been published and will not be repeated. Technical sessions were held Monday, Tuesday, and Wednesday evenings and Thursday morning. Excursions were arranged to Bingham and Garfield Tuesday; to Murray, Midvale, and Tooele Wednesday; and to Park City Thursday. The trip to Tintic, planned for Friday, was given up, though the picnic in Provo cañon was carried through as planned. Monday afternoon the organ recital at the Mormon Tabernacle was followed by an auto ride around the city; Thursday noon the gentlemen were entertained at lunch at the Ata Club; the evening of the same day the whole party enjoyed a swim in Salt Lake, followed by dinner and dancing at Salt Air; and Friday night there was a hilarious banquet to 350 members and guests at Hotel Utah. Everything possible to ensure the success of the meeting and to add to the pleasure of the visitors was done by the local committees, constituted as below:

General—R. C. Gemmell, chairman; D. C. Jackling, C. W. Whitley, C. E. Allen, Fred Cowans, Wm. Wraith, Walter Fitch.

Transportation and Accommodation—Duncan MacVichie, chairman; L. Hanchett, C. F. Moore, Frank Anderson, Robert S. Lewis.

Program—Alfred Frank, chairman; L. S. Austin, R. H. Bradford, W. A. Wilson, Edward Zalinski.

Entertainment—C. W. Whitley, chairman; Henry Krumb, A. K. Tiernan, C. H. Doolittle, J. A. McCaskell.

Press—Ernest Gayford, chairman; G. W. Riter, G. T. Hansen.

Ladies' Entertainment—G. B. Wilson, chairman; J. C. Dick, J. C. McChrystal, Stanley C. Sears, Mrs. Edwin F. Holmes, Mrs. C. W. Whitley, Mrs. Stanley C. Sears, Mrs. J. C. McChrystal, Mrs. Herman A. Prosser, Mrs. R. C. Gemmell, Mrs. G. B. Wilson, Mrs. J. C. Dick.

The Welcome on Monday

The first technical session was held Monday evening at Hotel Utah, R. C. Gemmell presiding. D. C. Jackling gave the principal address of welcome, closing with a brief résumé of the history of mining in Utah, abstracted below:

Mining in Utah, by D. C. Jackling

The first mine was discovered in Beaver county in 1860, and was called the Lincoln. The first recorded location was that of the Jordan mine, on September 17, 1863, in what is now known as the West Mountain mining district, Bingham Canyon.

No active interest in mining was shown until after the arrival in Salt Lake in October, 1862, of General (then Colonel) Patrick E. Connor, in command of the California Volunteers. He was eager to promote the mining industry. In December, 1863, he drew up a set of mining laws, and called a meeting of miners at Gardner's mill, on the Jordan river. At this meeting these laws were adopted, and Bishop Gardner was elected recorder of the first mining district of Utah, called West Mountain, in which the town of Bingham is now situated. In the summer of 1864 the first company, called the Jordan Mining Co., was incorporated under the laws of California, and an adit was driven into the property at a cost of $60 per foot. At this time blasting powder cost $25 per keg, and there were instances of it having brought as high as $100 per keg.

Silver-bearing lead ore was discovered by the prospectors of General Connor's expedition at Wasatch, Little Cottonwood, and at Mountain lake, in the year 1864. Owing to the completion of the Union Pacific railroad in 1869, and the excitement attendant upon the successful, but in some respects unfortunate, exploitation of the Emma mine, which was sold to an English company for a large sum, there was a great revival of mining activity in Utah, and by the close

of the year 1870 the organization of mining districts had been extended well over the state. In 1870 and 1871 a number of small smelters were built, and by the end of the latter year the total capacity of all such plants in the territory was 666 tons daily.

It so happened that the West Mountain district, the first one organized, was destined to become the greatest metal producer of any district in the state of Utah. The Utah Copper Co. was organized in 1903, and in the early part of the year 1910 it acquired the properties of the Boston Consolidated Mining Co. The Ohio Copper Co. was organized in 1903 to take over the Columbia mine and some adjacent claims.

The total value of the metal production of the West Mountain mining district to the close of the year 1913 is estimated at about $215,000,000.

Park City is in what was formerly known as Parley's park, and the Parley's Park district was organized in July, 1868. The first location was made on December 23, 1868, and the first shipment of ore was made in July, 1870. The first important producer, the Ontario mine, was discovered and located on June 15, 1872. This mine immediately became famous for its high-grade silver ore. During its more active life its output of silver totaled over $34,000,000, and it paid dividends amounting to nearly $14,000,000. In general, the ores in Park City are lead ores, carrying some zinc and relatively high values in gold and silver. It is estimated that the total value of the metal production of this camp at the end of the year 1913 is about $150,000,000. The mines have paid in dividends something over $40,000,000.

The Tintic district was organized December 13, 1869. Two of the largest mines, the Mammoth and the Eureka Hill, were located in the year 1870. The value of its total metal production up to the end of the year 1913, according to data procurable, was about $150,000,000, and the total of dividends paid up to that time was about $30,000,000.

The Alta district was productive of a considerable tonnage of high-grade silver ore.

According to the reports of the United States Geological Survey, the production of copper in Utah has increased from 100,000 lb. in 1870 to 161,445,962 lb. in 1913, and the total production for the 44 years is 1,135,498,000 lb., valued at $167,168,711. Of the 161,000,000 lb. produced in the state during 1913, about 144,920,000 lb. may be credited to the Bingham district, and about 120,000,000 lb. to the single largest company operating there. It is safe to say that the total value of the metals that have been yielded by the mountains of Utah and added as new and permanent wealth of the country is more than $635,000,000.

The technical men, many of them members of this Institute, who have been associated in Utah with this industry and its development, have done much in the way of contribution to general knowledge in scientific mining and metallurgy, as well as in the application of advanced methods to operating practice. These men should share distinction with those of practical training and skill in mechanical and other lines, who have learned their lessons in the application of natural laws at the exacting but thorough school of experience. Among both classes are the honored names of many who have deserved and won distinction in their several lines of effort.

Utah engineers and industries have done much toward the development of concentration appliances and methods as they are now used in the concentration of the low-grade so-called porpbyry copper ores here and elsewhere in the West, and in Utah there are by far the largest concentrating mills on earth. The engineers of Utah have developed and put into general use many appliances and methods which have become almost universal necessities in the commercial application of mining and metallurgical engineering. Altogether, Utah is proud of her mineral resources and history.

This address was followed by a number of papers dealing with leaching of copper ores, including particularly a series presented by Frederick Laist, 'Experimental Leaching at Anaconda' (Laist and Aldrich), 'Precipitation of Copper from Solutions at Anaconda' (Laist and Frick), and 'The Slime Concentrating Plant at Anaconda' (Laist and Wiggin). These papers provoked a brief discussion followed by an elaborate series of lantern pictures of sections of Butte ores, given by J. C. Ray of Stanford University. These views emphasized the large part in the study of ore deposits now played by polished sections and the progress made since William Campbell undertook to use the methods of metallography to solve problems in geology.

Smelting Problems on Tuesday

Tuesday evening the interest again centred on smelting problems. The session was presided over by William Wraith. The following papers were presented:

'Electrical Fume Precipitation at Garfield,' W. H. Howard; discussed by F. G. Cottrell, E. M. Dunn, and Lyman Bradley.

'Effects of the Bag House on the Metallurgy of Lead,' L. D. Anderson, with discussions by the author.

'Nodulizing Blast-Furnace Flue Dust,' Lawrence Addick; discussions by R. M. Draper and James H. Payne.

'Lead Smelting at East Helena,' E. L. Newhouse, with discussion by the author and G. C. Riddell.

'A Comparison of the Huntington-Heberlein and Dwight-Lloyd Process,' W. W. Norton; discussed by A. S. Dwight and G. C. Riddell.

'The International Lead Refining Plant,' G. P. Hulst, with discussion by the author.

'Smelting Lead Ores in the Blast-Furnace,' Irving A. Palmer, and 'The Bag House in Lead Smelting,' H. H. Alexander, were read by title.

'Chloridizing Leaching at Park City,' T. P. Holt, with discussion by F. S. Schmidt.

The use of sintering machines provoked considerable discussion. At the East Helena plant, according to Edgar L. Newhouse, 6500 tons of lead per month is made, and this is probably more lead than the output of any other lead smelter. Dwight-Lloyd sintering machines have been used since 1907. Gases from both sintering and blast-furnace departments are trapped in a bag house, being neutralized by use of zinc oxide. Blast-furnace matte is pre-roasted in Godfrey furnaces, mixed with the direct converting mixture, and blown in Huntington-Heberlein pots. On the whole, the Dwight-Lloyd machines are preferred. At the Murray plant both are used side by side, and were studied with much interest by the visitors the next day. An interesting comparison of the work of the two was made by W. W. Norton.

The chloridizing leaching process used by the Mines Operating Co. at Park City, and described by Mr. Holt, created much interest both at this session and on the occasion of the visit of the party to Park City on Friday. A full account will be printed later.

Zinc Losses and Treatment on Wednesday

Wednesday evening, C. W. Whitley presided. Before taking up the regular program, W. L. Saunders announced the plans of the entertainment committee that has been formed by coöperation of the five national engineering societies, to care for foreign visitors in 1915, and bespoke the active coöperation of all members of the Institute. It is planned to afford the visitors every opportunity to visit American mines and works while they are on their way to and from the Panama-Pacific Exposition at San Francisco. He was followed by H. Foster Bain, who told briefly of the progress of the Exposition and the International Engineering Congress, of which the Institute is one of the guarantors. The regular program centred on the problems of zinc mining and treatment, and the session was notable for the amount and variety

of the discussion invoked. The especial papers read were:

'Losses of Zinc in Mining, Milling, and Smelting,' by Dorsey A. Lyon and Samuel S. Arentz.

'Separation of Lead, Zinc, and Antimony Oxides,' by R. D. Divine.

'Electrostatic Separation at Midvale,' by H. A. Wentworth.

'Treatment of Complex Ores,' by S. E. Bretherton.

Technology and Excursions on Thursday

Thursday morning, about 40 of the local members of the Institute met and formed a Salt Lake section, which promises to become one of the most active in the Institute. At the technical session following, the papers read dealt with a large range of mining and metallurgical problems. The list included the following, a part being presented by title:

'The Ajo Copper Mining District,' by I. B. Joralemon.

'The Occurrence of Bournonite, Jamesonite, and Calamine at Park City,' by Frank R. Van Horn.

'Descriptive Technology of Gold and Silver Metallurgy,' by A. W. Allen.

'Playa Panning on the Cauca River,' by W. F. Ward.

'The Dorr Hydrometallurgical Apparatus,' by J. V. N. Dorr.

'Discussion of James Johnston's Paper on the Mill and Metallurgical Practice of the Nipissing Mining Company, Ltd., Cobalt, Ontario, Canada,' by G. H. Clevenger.

'Tests of Rock Drills at North Star Mine,' by R. H. Bedford and William Hague.

'Draining Kerr Lake,' by Robert Livermore.

'The Design, Construction, and Cost of Two Mine Bulkheads,' by Sidney L. Wise and Walter Strache.

'Methods and Economics in Mining,' by Carl L. Allen.

'The Appraisal of Coal Land for Taxation,' by H. M. Chance.

'Mining Claims Within the National Forests,' by E. D. Gardner.

'Biographical Notice of Louis Janin,' by R. W. Raymond.

'Development of the Round Table at Great Falls,' by Arthur Crowfoot.

Mr. Clevenger gave a very interesting account of later developments in metallurgical practice at Cobalt and of the reasons back of each step. Messrs. Bedford and Hague showed how the Paynter rock-drill testing machine (described in the *Mining and Scientific Press*, August 2, 1913) enables an operator to weed out poor drills and to determine the conditions of maximum efficiency for those retained in service. In discussion, W. L. Saunders pointed out that the particular tests presented could hardly be regarded as fairly representing the drills under competitive conditions, since the drills were not all of modern type and the service required in a heading differs so greatly from that in a stope. He, however, commended the use of the machine and all other devices that lead to more intelligent use of drills.

A large party from the Institute spent the day at Park City, where the visitors were first taken to the Silver King to see both the mill and mine. Lunch was served in the new and really beautiful underground hoisting chamber in the Alliance tunnel. The Wellman-Seaver-Morgan hoist which here serves the lower levels, came in for close examination and will be later described. The underground chamber is remarkable for its size and the attention to detail shown in its construction and finish. Even the lighting is by the modern indirect system. From the Silver King a number of the visitors went to other properties, especially to the Ontario, where the Mines Operating Co., under management of George Dern and technical direction of T. P. Holt, is working the old stope fillings by an ingenious improvement upon old methods.

Friday and the Banquet

Friday there were no technical sessions, though there were numerous conferences and a picnic, as already noted, in Provo cañon. In the evening, the meeting closed with a complimentary banquet served to 350 people in the large grill room of Hotel Utah. The committee seated people as far as possible by colleges, so that between eating, drinking, and dancing, college yells and college songs were frequent. W. L. Saunders, as toastmaster, was delightful after Messrs. Gemmell and Matthewson had argued him out of reading the whole of a 936-page speech he professed to have prepared for the occasion. Mr. Thayer as president responded to the toast to the Institute. Mr. Stoughton discussed 'Institute Ideals,' and the Governor of Utah, William Spry, spoke of the glories of his state. Colonel E. M. Allison spoke entertainingly of 'The General State of Affairs,' and the session closed with dancing while everyone hummed the catchy refrain of the song of the Utah University boys:

"They say that them Mormon boys ain't got no style,
But they've style all the while, style all the while."

The members registered were as follows:

J. O. Ambler, L. Addicks, L. S. Austin, J. B. Ambler, D. S. Arentz, C. W. Adams, Jr., C. E. Allen, L. D. Anderson, W. W. Atwood, Frank Anderson.

Linn Bradley, H. L. Brown, F. H. Bostwick, T. B. Burbridge, G. S. Brooks, P. F. Barnwell, J. J. Burt, F. B. Bodfish, D. C. Bard, C. H. Bowman, J. K. Bryan, R. H. Bradford, C. L. Berrian, L. E. Brown, Alex Bowie, Wallace D. Bowie, A. C. Boyle, Jr., C. M. Bell, E. S. Bordwell, F. C. Bliekensderfer, J. L. Bordman, H. F. Bain, George D. Blood, Robert H. Bedford, R. N. Belt, W. A. Barnes, R. G. Bowman, J. J. Beeson, S. E. Bretherton, D. W. Brunton, O. E. Bradley, W. J. Bowdwin, T. P. Billings.

W. W. Case, Jr., R. C. Canby, W. E. Corne, G. H. Clevenger, W. J. Cox, W. R. Cody, W. L. Creden, T. B. Crane, G. W. Crane, H. H. Clark, David Cole, Will L. Clark, L. M. Cargo, J. H. Cooke, A. E. Carleton, William Coumerlih, E. W. Clark, Fred Cowans, H. E. Crawford, H. H. Chisholm, Joseph A. Carson, F. G. Cottrell, J. M. Callow, W. B. Cole.

L. A. Dunham, E. W. Durfee, C. H. Doolittle, J. C. Dick, R. C. Doggett, C. S. Drew, E. M. Dunn, B. H. Dunshee, J. V. N. Dorr, William Dempster, George H. Dern, P. J. Donohue, A. M. Day.

H. R. Ellis, F. B. Ely, R. Emanuel, E. C. Engelhart, R. J. Evans, C. W. Earl.

B. J. French, M. Fulnerty, Walter Fitch, Walter Fitch, Jr., Cecil Fitch, Howard Fitch, W. B. Fisher, F. R. Field, Alfred Frank, W. C. Ferguson, E. P. Fleming, C. R. Forbes, Allan J. Fairbairn.

A. O. Gates, R. J. Glendinning, E. Gayford, N. B. Gatch, Walter Gaby, W. E. Greenough, F. T. Greene, C. W. Goodale, H. C. Goodrect, L. D. Goodshall, C. H. Gibbs, Edw. Greenleaf, R. J. Goodwin, R. C. Gemmell, H. A. Guess, A. E. Gartside, R. Guyer, William W. Graves.

W. L. Henderrech, J. M. Hyde, J. B. Herreshoff, G. P. Hutsch, A. B. M. Hodges, V. C. Helkes, W. H. Hendrickson, J. B. Hastings, F. B. Hill, L. O. Howard, E. C. Hickman, W. H. Horton, H. J. Hermann, G. T. Hansen, D. G. Hansen, J. S. Hauerman, William Hague, J. T. Hodson, Stuart Hazlewood, R. W. Hyde, V. A. Hart, R. H. Hawley, Barry Hogarty, L. Hanchett, H. W. Hardinge, Harloye Hardinge.

S. A. Ionides.

E. P. Jennings, C. W. Jewett, F. H. Jenks, M. M. Johnson, E. R. Jones, J. F. Johnson, Sidney Jennings, J. C. Jones, D. C. Jackling, Thomas A. Janney, Arthur W. Jenks.

G. R. Kittle, B. N. Kilbourne, E. W. Keith, J. Kojima, Henry Krumb, John McG. King, H. S. Knight, S. J. Kidder, M. P. Kirk, O. M. Kuchs.

F. G. Lazier, W. Lindgren, L. C. Lennox, D. A. Lyons, David Lemmon, F. A. Linforth, E. R. Lidvall, G. Lavagnino, Fred Laist, Alex Leggatt, G. W. Lambourne, C. B. Lakenan, C. L. Larson.

Walcott, R. E. Wells, Jr., William Wraith, J. H. Winwood, E. H. Wilson, William A. Wilson, A. C. Watts, E. H. Walker, G. H. Williams, F. V. Westcott, Col. E. G. Wall, W. C. Wolf, George F. Waddell, E. M. West, Robert Wallace, H. D. Woolfenden.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

PRODUCTION OF ZINC IN ENGLAND, WORKS OPERATED AND RESULTS OF AUSTRALIAN COMPANIES.—PRESTEA BLOCK A MINE OF WEST AFRICA, POOR RESULTS.

For some years the extraction of zinc from ore has been a decaying industry in England. The domestic supply of material has gradually diminished. Vivian's, of Swansea, continue to keep their works going at Morriston on imported ore; Williams, Foster & Co. have a modern plant near by, but the Company is owned by the Metallurgische Gesellschaft of Frankfort; and another neighbor is the English Crown Spelter Co., which smelts ores mined in the north of Italy. The only recent new venture has been the Central Zinc Co., which was formed eight years ago to establish smelting works in England for the purpose of treating zinc concentrate produced at the Central mine belonging to the Sulphide Corporation at Broken Hill. The idea was to avoid selling to German and Belgian buyers. The only other company at Broken Hill that treats its own product is the Proprietary. Whereas the policy of the latter was to make zinc on the spot, the Sulphide Corporation decided to smelt in England, where labor conditions were more favorable, supplies cheaper, and the market for the metal nearer at hand. Unfortunately, both enterprises have been comparative failures. The Proprietary produces 90,000 tons of zinc concentrate per year averaging 46% zinc, and treats about 12,000 tons locally. The number of furnaces in use depends on the labor supply. Anyone connected with zinc operations knows that they are not fool-proof, and that they require much closer watching and regular attention than most metallurgical processes. The Sulphide Corporation has been even more unfortunate than the Proprietary. The capital of the Central Zinc Co., £150,000, was subscribed in cash by shareholders in the Sulphide Corporation, and the whole of the money was used in building the works. A contract to last for ten years was made whereby the Sulphide Corporation would supply 50,000 tons of zinc concentrate per year, and would guarantee a dividend of 5% in consideration of receiving one-third of the profits. When the plant was first designed it was intended to have a capacity of 40,000 tons per year. These estimates have been hopelessly at fault, as the yield of metallic zinc, starting at 1118 tons in 1909, has increased only slowly upward until it arrived at 3486 tons, extracted from 9870 tons, during 1913. The local conditions during the last year have been all against the Company, as the cost of freight from Australia has increased, as also has the price of coal, while the price of zinc has fallen. One trouble all these years has been the scarcity of labor suitable for the work. As regards the shareholders in the Central Zinc Co., they have received the 5% as guaranteed, and the Sulphide Corporation has seen little for its third share in the profits; but as the shareholders in the two companies are largely the same, the relative position matters little. The point is that not a quarter of the expected amount has been smelted, and that no profit has been made on the smelting.

In the London letter of last week I referred to a large low-grade proposition in Rhodesia, the Shamva, that is providing food for critics. This week we have the Prestea Block A, one of the important mines in West Africa, that has absorbed immense amounts of capital and never paid a dividend. The Company was formed by Edmund Davis, one of our champion promoters, in 1903. Milling commenced in 1906, but was suspended from 1909 to May 1911, pending additional development. In 1909, Wernher, Beit & Co. subscribed for 200,000 new £1 shares at 24s., and later took 50,000 at 27s.6d. Subsequently 70,000 shares were taken by shareholders at 27s.6d. each, and 30,000 shares at 32s.6d. each. Part of these funds was devoted to the building of a new mill. In January 1911 the property of the Prestea company was absorbed in exchange for 199,876 shares. As still further capital was required, £150,000 was advanced on loan by the Central Mining & Investment Corporation and the Fanti Consolidated. Hugh F. Marriott is consulting engineer, acting for the Central Mining, and William Crosley is manager. During 1913, 229,990 tons of ore was raised and treated, an increase of 57,000 tons as compared with 1912. An average of 80 out of 110 stamps were at work. The yield by amalgamation was 64,593 oz., 4408 tons of concentrate was roasted and cyanided, yielding 19,324 oz., and 171,461 tons of sand was cyanided for 7122 oz., making a total of 91,039 oz., worth £386,918, or $8.06 per ton. The average assay of the ore treated was $9.96, so that the recovery was 81%. The gold left in the sand was $1.62, and in the concentrate residue $5.54. The slime, amounting to 54,121 tons, averaging $2.54 per ton was not treated, but is being accumulated for future consideration. The metallurgical difficulty at this mine is the presence of graphitic shale in the country rock. Experiments are being continued with a view to improving the extraction, and the advice of W. R. Feldtmann, who has had a similar problem at the Ashanti Goldfields Corporation, has been sought. During the year, the main shaft has been sunk to 938 ft., and the north shaft to 1024 ft. Development totaled 5560 ft., and 81,623 tons of ore averaging $7.32 was disclosed. Ore reserves on December 31 were estimated at 691,670 tons averaging $9.92, compared with 835,014 tons averaging $10.66 the year before. The cost during the year, including interest on loan and depreciation of plant, was £348,593, or $7.28 per ton. The balance of profit was £38,340, which was carried to the balance sheet. During the year, the loan was reduced by £25,000, and now stands at £125,000, which is to be liquidated as to £50,000 on or before December 31, 1915, and afterward, as to the remainder, in monthly installments of £2500. The issued share capital is £1,049,876. The lending companies have options on an additional 100,000 shares at par. The present state of this company gives much cause for anxiety, as may be judged by the fact that the shares of £1 nominal value, but subscribed many of them at 30s., stand at only 10 shillings.

JOPLIN, MISSOURI

PRODUCERS EXPECT BETTER ZINC ORE PRICES AS RESULT OF EUROPEAN WAR.—STRIP-PIT MINING ACTIVITIES—BELLEVILLE-KLONDIKE DISTRICT.—TECUMSEH MINE.—GRANBY COMPANY.—WEST MIAMI DISTRICT.

Zinc ore prices throughout the Missouri-Kansas-Oklahoma district are at low ebb, $38 to $40 being the basis price of blende carrying 60% metallic zinc, compared with $44 to $47.50 in the corresponding week of 1913. Producers, however, anticipate better offerings as a result of the European war. Its effect on the zinc industry, it is thought, cannot be deleterious. Reasons for this belief are that Europe produces approximately

66% of the world's spelter, the United States producing the remainder, with the exception of insignificant tonnages from other countries. The annual production of spelter is close to 1,000,000 tons, and while the production in European countries, especially Germany, will probably be decreased because of the war, the demand for spelter in the countries of Asia and Australia will doubtless continue, and the supply that has been furnished by Europe in the past cannot be expected to meet the requirements in the future. The United States produces barely enough spelter to meet its own requirements; but a greater production could be recorded if prices were high enough to enable the smelters to pay a higher price for zinc ore. This, in turn, would result in the opening of many mines in this district, which would produce a large tonnage at a profit, but which cannot be operated at present prices without a loss.

The first 'strip-pit' zinc mining operations in this district, in which there had not been a previous caving of ground which necessitated open-air work, have been launched by J. H. Moreland and associates, on a lease of the Oak Hill Mining Co.'s land, northwest of Joplin. Drilling showed a disseminated orebody beginning at a depth of 30 ft. and continuing down to 140 ft. The overburden was of such a character that it could not be expected to form a substantial roof, and as the orebody had every indication of being extensive, it was decided to put a steam-shovel at work excavating an open-pit, which will be 100 ft. wide by 200 ft. long, when operations are first started. The pit is now 100 ft. square, and has been excavated to a depth of 20 ft., the surface soil being removed. After 10 ft. more of excavation, the size of the pit will be doubled and active mining started, the ore being taken up an inclined tramway to the mill. A recovery of 3% is expected, although there are richer streaks that carry as high as 8% blende.

The Belville-Klondike district, five miles northwest of Joplin, once a famous producer of high-grade zinc ores, but in recent years of little importance, is being rejuvenated, and a number of pumping plants are at work draining the water to greater depths than previous mining operations. The Geronimo Land & Mining Co., operators of other large properties in the district, has a large pumping plant running. Several drill holes have been sunk into ore at this point. Another pumping plant is at the Walnut Hollow mine. The general depth of the ore seems to be about 120 ft. It was from the Walnut Hollow property that the largest piece of lead ore in the district's history was taken.

An unusually high mill recovery is being made at the Tecumseh mine, operated by Homer Seals and associates, on a lease of the Connor land at Thoms Station, the output of concentrate being better than 10% of the 'crush' ore treated. The grade of the concentrate is not high, but is improving as operations are extended deeper. The mine made its initial turn-in a few weeks ago. It was only a few months in developing from a drill prospect to a producing mine, and several drifts are now into ore carrying both blende and galena at a depth of 148 ft. Good ore still in the bottom of the drifts will result in this being stoped later. The Company is turning out concentrate at the rate of 15 tons per shift. The mill formerly was operated by the Rich-In-Ore Mining Co. on a nearby lease.

The Lynas Mining Co., of Kansas, is raising ore from a shaft sunk on Missouri land. The shaft is on an island in the centre of Spring river, seven miles west of Joplin, and the grade of ore is reported as good.

Drilling in virgin territory is being conducted by B. P. Ellis and associates who have a lease on the Reding & Clark land near the mouth of 'Touch-Me-Not Hollow,' 8 miles south of Joplin. Ore at two levels has been proved by two holes put down, the upper body being at 100 ft., and the lower at 250 ft. No mining of importance has ever been conducted near this tract.

The Granby Mining & Smelting Co. is operating a new concentrating plant known as the B. & H. Heretofore the Company has confined itself to leasing operations exclusively. Its willingness to engage in active mining is considered a favorable argument in favor of the profits to be derived from zinc and lead development in this district.

One of the largest pumping plants in the district, that of the Dallas mine, west of Carl Junction, Missouri, which recently was suspended because of needed repairs, has resumed operations. The Company has a shaft to a depth of more than 200 feet.

Development in the West Miami, Oklahoma, district where ore is encountered within 50 ft. of the surface, is proving the necessity of extensive timbering. Several bad cave-ins have occurred. The ore is rich in zinc and lead and is found in unusually soft ground. One concentrating plant, that of the McConnell & Barnes Co., is in operation and another is planned to be erected by O. W. Sparks and associates.

PLATTEVILLE, WISCONSIN

JULY PRODUCTION HEAVY, BUT LITTLE PROFIT.—ORE PRICES.—CARBONATE OF ZINC ORES.—DISTRICT OUTPUTS.—FUTURE FAIRLY ENCOURAGING.

July has for years been noted as the banner month of the year for this field in production of zinc ores, and this year proved no exception, although as compared with former years more drawbacks were experienced than ever before. The general depression manifest in many industries over this country has affected ore prices to such an extent, that producers claim the margin of profit is almost negligible. The smaller independent operating concerns have almost all been eliminated from the calculation. The fairly good showing in output now being maintained is coming almost exclusively from smelter owned mines, or foreign corporations. Little ore has been offered for open market bidding, contract deliveries to smelters or production going direct from smelter owned mines to furnaces, now being the rule. Medium and low-grade ore suffered from the fluctuation in prices during the month, more than finished high-grade concentrate which seemed to be in good demand. Prices during the month ranged from $34 to $40 per ton of 60% zinc, and closed at $36 to $41 per ton, some premium ore going at the high figure. Production of raw concentrate showed a considerable increase over the output of the month preceding, and the reserve held at the beginning of the month, in excess of 6000 tons of all grades, was reduced considerably by heavy unloading on the part of the Wisconsin Zinc Co., which carried more than half of the surplus product. More high-grade separator product was marketed due to the activity during the month of an electro-static separating plant at Cuba, which had been idle for two years, and now the property of the Wisconsin Zinc Co. The Mineral Point Zinc Co. also showed increased activity in the refining of crude ore at the Company's works at Mineral Point.

Lead ore was in poor demand all the month, and sales were very light. Bids were submitted at $45 and $46 per ton, but producers preferred to hold this grade of ore, and the few sales reported were made by managements requiring funds to meet current obligations and payrolls. The production of pyrite fell off considerably, due to off markets, and only one producer endeavored to make any showing at all, the ore coming from the Wilkinson mine at Benton, and going to the Grasselli Chemical Co., East Chicago, Indiana. Producers of 'dry-bone,' as carbonate of zinc ore is termed in mining circles in this field, were not given a market for this grade product until the closing days of the month. The ore is used exclusively in the manufacture of oxide of zinc, and now finds increased demands from the automobile industry. The Mineral Point Zinc Co. is the largest manufacturing concern engaged

in the production of this commodity, and has secured control of the northern districts, where this ore is in great beds, by investments in lands, mines developed and in operating order and leaseholds, easily aggregating $1,000,000. A heavy production of carbonate zinc ore is looked for from these districts, in order that the new steel plant recently constructed at Mineral Point, Wisconsin, at a cost of $1,500,000, may be supplied. Much low-grade calcined blende ores, silicate of zinc from the Missouri districts, and carbonates of zinc from the western states are imported to keep the plant engaged in the manufacture of oxide moving. Besides, while blende has been battling with declining markets, prices on carbonate and calamine ores are as good as ever, and now that much of the imported material has been exhausted a big production is expected from the mines of the northern camps in this field.

Shipments of ores by districts, for this field, were reported during July as follows:

Districts.	Zinc, pounds.	Lead, pounds.	Pyrites, pounds.
Benton	7,782,000	80,000	1,948,200
Galena	4,908,000	152,400	.....
Shullsburg	2,926,000	.....	.....
Hazel Green	2,862,000	.....	.....
Livingston	2,670,000	.....	.....
Cuba City	2,452,000	.....	.....
Harker	2,156,000	.....	.....
Linden	1,080,000	61,490	.....
Platteville	984,000	.....	.....
Highland	738,000	.....	.....
Montfort	224,000	.....	.....
Mineral Point	120,000	.....	.....
Dodgeville	.....	80,000	.....
Mineral Point Zinc Co.	3,560,900	.....	.....
Total	32,462,900	373,890	1,948,200

The gross production of green concentrate reported from all mines during the month aggregated 25,492,590 lb. and net deliveries of refined ores from all separating plants direct to smelter 15,617,890 lb. The Mineral Point Zinc Co. delivered 45 cars of high-grade calcined ores to smelter at De Pue, Illinois. Exceptionally heavy deliveries were made from the Wisconsin Zinc Co.'s mines to separating plants at Cuba and Platteville. All the ores reported from these two points were high-grade finished product. Operators at several points, responding to interviews, claim that although still greater declines may be manifested in both ore and metal markets, the present production will be fairly well maintained.

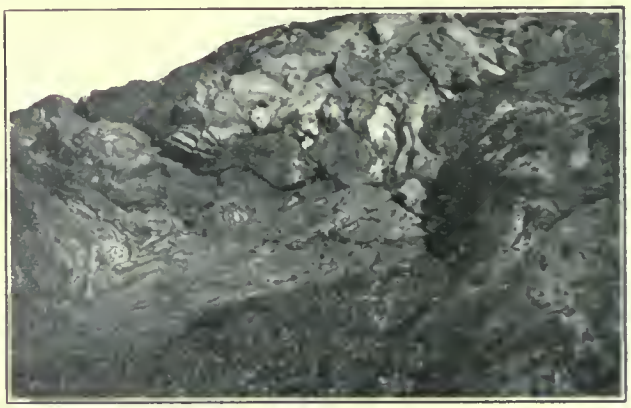
IRON RIVER, MICHIGAN

MINE ACCIDENT THROUGH QUICKSAND.—DISTRICT NEWS.—IRON ORE BUSINESS IMPROVING.—ORE TO NOVA SCOTIA.—IRON ORE LANDS.—ZIMMERMAN MINE.—TAXES.—MINE EQUIPMENTS.

A bad mine accident occurred at the new Balkan mine of Pickands, Mather & Co. at Alpha, in the Crystal Falls district, recently, when seven miners were caught and killed by a sudden rush of quicksand. A raise 60 ft. high gave way without any warning, letting in a great flood of quicksand and water from near the open-cut workings, which are being stripped by two steam-shovels. Twelve miners were working near the raise, of whom five just escaped to the shaft, one being rescued out of the quicksand after cutting away his clothes and boots. The mine is to be worked partly by open-cut and partly by underground methods, and a shaft 500 ft. deep has been sunk north of the open-cut with a main drift running south, and two cross-cuts in one of which the raise was situated. The seven miners killed were foreigners. Some years ago at the Mansfield mine, also in the Crystal Falls district, the bottom dropped out of the Michigamme river, flooding the mine and killing 29 men. During the past weeks, trouble has resulted at several of the Michigan iron mines due to heavy rains.

The village of Stambaugh in the Iron River district is to have a new $12,500 Carnegie library; Iron Mountain, on the Menominee range, already has one. Chase S. Osborn, who was the first governor of Michigan from the mining district of the upper peninsula, but who aroused enmity among the mine operators by his advocacy of the Finlay tax system, is again campaigning for the Republican nomination. Mr. Osborn, originally a newspaper man, has been connected with the mining industry of Michigan for a number of years.

As predicted, the iron ore business, which has been unusually dull this season, is beginning to pick up a little, and signs of a revival during the latter half of the shipping season are apparent. Several companies have now begun to



FOLDED PRE-CAMBRIAN ROCKS NEAR ISHPEMING, MICHIGAN.

ship their large stockpiles which accumulated during last winter, and additional miners are being employed to restore forces to their original number. Among the mines which are increasing in activity are: Ernst mine of Florence Iron Co. at Commonwealth, Wisconsin; Wickwire mine of Wickwire Mining Co. at Iron River; Baltic and Zimmerman mines at Iron River; the Newport mine of Ferdinand Schlessinger at Ironwood (which has employed 120 extra men); the Ashland mine of the Hayes Bros., also on the Gogebic range; the Pewabic mine at Iron Mountain; Portland mine of Rogers, Brown & Co. at Michigamme. The two largest operators in Michigan, the Oliver Iron Mining Co. (subsidiary to the U. S. Steel Corporation), and the Cleveland-Cliffs Iron Co., are still going light.

A trial shipment of 1200 tons of iron ore was recently shipped from Escanaba on Lake Michigan to Sydney, Nova Scotia, by a Canadian steamer, the distance being 1750 miles. It is proposed to mix the ore with Newfoundland ore for furnace use. Some prophets see in the disposal of the Republic mine and iron ore lands on the Marquette range by the Cambria Steel Co. to the Cleveland-Cliffs Iron Ore Co., a sign that a reaction has set in against the steel and iron manufacturers at the lower lakes owning iron ore mines, on account of the uncertainty and difficulties of complicated mining propositions. It is true that during the past ten years there was a scramble of furnace interests from Cleveland, Buffalo, and Chicago to take up iron ore lands at Lake Superior, preferring to produce their own ore rather than buy it in the open market; and it is also true that, in spite of several lucky developments by rather innocent arrivals, some of the newcomers became involved in doubtful propositions and in bothersome lawsuits, etc., but it is probably true that in spite of the increased difficulties of mining iron ore, due to exorbitant taxes, accidents, natural inconveniences, and in spite of reduction of ore prices in the

open market, the various furnace interests will hold on to what they have got. Eugene Zimmerman, of Ohio, who came to Lake Superior several years ago to look for an iron mine, and found a large and valuable one under the noses of operators at Iron River, has lost the lawsuit brought against him by Paul Schook, a saloonkeeper of Crystal Falls, whereby Schook will receive 4c. per ton (a one-third royalty) on all ore mined at the Zimmerman mine during the continuance of the 30-year lease, and will have a sum of $30,000 due from back royalties. If the Zimmerman mine comes up to expectations with several millions of tons of ore, Schook will receive eventually from $100,000 to $200,000. Schook claimed that he helped Zimmerman to secure the lease, and that the latter promised to 'whack' with him. This Zimmerman denies, but states that he would "like to whack Schook." He will appeal the case to the Supreme Court. The Zimmerman property has been in successful operation for a number of years and the present suit has attracted wide attention in the iron country.

The State Tax Commission, which is kept constantly on the move estimating the present value of iron ore deposits, according to expected profits and tonnage reserves, has scaled down the valuations of mines at Negaunee about $2,500,000, and the mines of the western Menominee range about $2,000,000. The mining companies are pleased, but the citizens and property owners in these districts are protesting.

Corrigan, McKinney & Co. will improve its Great Western mine at Crystal Falls, now idle for several years, by replacing the timber-lined shaft through 80 ft. of sand by a concrete shaft, and will replace the old head-frame by a new one with a crusher-stand built on a separate foundation, so the gyratory crusher will not shake the head-frame, as has been the case in the past. Jones & Laughlin will line the shaft at its Iron Mountain Lake mine, near Ishpeming, with concrete for a distance of 50 ft. to bedrock. The Thomas Furnace Co., of Milwaukee, a small iron manufacturer in an unusual location, has begun developments at the old Indiana mine near Iron Mountain, recently taken over from Captain Spencer, and has brought machinery from its old mine in the Baraboo, Wisconsin, district. The Huron Iron Mining Co., of Iron River, which went bankrupt, together with the McDonald mine at Crystal Falls of the same interests, is involved in settlement with claimants.

JOHANNESBURG, TRANSVAAL

RAND MINES, LTD., ANNUAL REPORT: VALUE OF ORE AT DEPTH. ORE MILLED, COSTS, EXTRACTION, DRILLS, AND AIR CONSUMPTION.

The feature of the second week in June was the annual meeting of the Rand Mines, Ltd., and the usual speech of the chairman covering the work, progress, and disappointments encountered at the mines, as this is the most important mining corporation on the Witwatersrand. The mines worked by this corporation extend from Roodepoort on the Western Rand to the last outcrop mine on the Far Eastern Rand, so that the chairman's annual review is to all intents and purposes a review of the year's mining on the Rand. The fact that this Company either controls or is interested in almost every mine of importance on the Rand also adds interest to the meeting, which is emphasized by the knowledge that the 12 mines under its control made last year a total working profit of £4,898,380. The ore reserves in these mines total 32,153,560 tons, and the estimated gold content amounts to £48,903,000. In his address the chairman attempted to minimize the importance of the following paragraph contained in a recent report issued by the Consolidated Gold Fields of South Africa: "There can be no doubt that there is a gradual decline in the average values over large areas of the ore developed as deeper sections of the Rand are opened up"—a statement he pointed out was only true in a limited degree. He further stated that it does not apply to the whole of the Rand, where in many large areas little or no impoverishment has so far taken place. In proof of his assertion that gold content does not always decrease with depth, the following two examples were quoted:

Level No.	Vertical depth, feet.	Footage sampled.	Average width of reef, inches.	Average value, dwt.	Inch dwt.
CITY DEEP					
2	2137	1705	21.6	44.9	970
3	2263	840	16.8	62.6	1052
4	2407	1640	21.5	28.8	619
5	2542	3215	35.0	19.2	672
6	2725	5680	30.6	13.8	422
7	2875	4980	31.7	15.8	501
8	3001	7125	33.7	16.0	539
9	3208	6440	34.7	13.3	462
10	3360	1997	35.8	11.2	401
11	3519	322	45.4	10.0	454
VILLAGE DEEP					
6, 7, and 8	2500 to 2700	10,665	38.2	10.4	397
16, 17, and 18	3760 to 4120	8,945	44.4	8.6	383
19	4189	280	39.3	8.1	318

It may be pointed out that both these mines are situated in the same part of the Central Rand, and that the details given above, while indicating a considerable area of profitable ground at a good depth from the surface, do not, on careful scrutiny, prove that Rand ores do not decrease in value with depth, but rather tend to confirm the generally accepted view that this is so as greater depths are reached. It is quite true that good ore is sometimes found as stated by the chairman at vertical depths of 4000 ft. and over, but taken over considerable and truly representative areas, it is the exception rather than the rule to find that the gold content is maintained in depth. The Cinderella Deep and Brakpan mines, quoted by the chairman as well known instances, are equally unfortunate with the City Deep and Village Deep; while the Hercules average value of 17 dwt. over 26 in. at a depth of 4361 ft. lies close to an extensive proved area where at a depth of 4000 ft. the average over a stoping width is only about 2 dwt. per ton, the Hercules shaft, as a matter of fact, intersecting the reef where it was admitted to be unprofitable. From one end of the Rand to the other, lower gold content with depth, as compared with the outcrop mines, can be seen wherever extensive mining operations have been carried on; but even then, there are numerous instances where limited areas contain a fair amount of profitable ore.

An interesting table quoted in the chairman's speech was that with regard to the marked reduction effected during the last four years in the costs of treating ore, the figures being as follows:

Year.	Tons milled.	Total cost.	Cost per ton.
1910	6,752,448	£1,505,381	$1.08
1911	7,595,192	1,681,953	1.06
1912	8,244,944	1,709,655	0.98
1913	8,444,480	1,549,034	0.88

This reduction is still being continued, and reflects considerable credit on F. L. Bosqui, the consulting metallurgist to the Rand Mines, Ltd., and also on his staff. The lowest cost on this group of mines was at the Crown Mines, where it averaged 72c. per ton milled. Extraction averaged 95.73%, the New Modderfontein plant being the highest with 97.2%.

One of the features in connection with the new plant to be erected at the New Modderfontein mine is the proposed abolition of the sand-collecting tanks, F. L. Bosqui being of the opinion that with the good classification of sand and slime now obtained by means of cones, the sand can be collected and treated in the same tank.

With regard to the efforts being made to reduce working costs on the Rand, mention was made of the increasing use of the lighter drills of the hammer type with the object of displacing not only natives, but the heavier piston drill. The comparative lightness and higher speed of drilling possessed by the hammer type are no small advantages, and when a suitable detachable bit has been devised, the superiority of these light hammer drills should be more pronounced than ever. It is estimated that, on grounds of economy, detachable bits ought not to cost more than 8c. each. Mention was also made of the saving effected in machine-drill maintenance amounting to £17,000 in 1913 compared with the previous year, while the saving in drill steel and sharpening represented another £13,000. Then again, for 1912, 137,044,567 units of compressed air was required for 931,978 drill shifts, an average of 147 units per drill shift, while in 1913, 133,435,038 units sufficed for 957,350 drill shifts, being a reduction to 139 units per drill shift. The contract price arranged with the Victoria Falls Power Co., Ltd., of 1.05c. per electric and air unit has been reduced by rebates given on account of the reduction in railway charges for carrying coal, and further savings are expected when a 25% share of the surplus profits of the power company become available to the mines.

WASHINGTON, D. C.

LEASING OF COAL LANDS OF ALASKA INCLUDED IN NEW CONSERVATION PROGRAM.—RADIUM BILL.

The conservation program, on which the House of Representatives has entered by a special wish of the Wilson administration, embraces no legislation detrimental to mining, but not at all what the mining world has had more at heart, the creation of a commission to codify the mining laws of the land. This must take its chances in the ruck of legislation. The conservation scheme includes five bills, and all of them are at least somewhat related to mining by propinquity, such as the bill to provide for the development of water-power, and the use of public lands in relation thereto; and the bill extending the period for the payment on reclamation projects. The mining bills were three in this program. One provides for the leasing of coal lands in Alaska, and the House arranged six hours of general debate on this.

The known coal-bearing ground of Alaska includes 16,000 square miles, and 1210 miles of this is asserted by the U. S. Geological Survey to be workable coal beds, 12% of the coal lands being anthracite. There are some valuable bituminous areas. The most important field is the Bering River. The United States reserves to itself 5120 acres of this field, and 7680 acres in the Matanuska field. The leased lands are to be divided into blocks of 40 acres each, and in no case exceeding 2560 acres in any one block and these blocks will be leased through advertising and competitive bidding. The leasing, it is hoped, has been made in such form as to permit the most economical mining of the coal. Provided the combined areas do not exceed 2560 acres, there may be new leases for additional lands. There may be also a consolidation of leases within the 2560 acres limitation. The Secretary of the Interior will fix the royalty which shall not be less than 2c. per ton, and the royalty will be turned into a fund for the benefit of Alaska. The lands withheld for the United States will be for the purposes of the army, navy, and other Government uses.

The radium bill, previously described, was the second of the mining bills on the program, but it stands little chance of passage in the Senate, whatever the House may do with it. There has ceased to be any considerable enthusiasm over radium since it has not been found the cure for cancer. The third bill takes up the authorization of exploration for and disposition of coal, oil, gas, potassium, and sodium.

NEW YORK

HOW THE METAL SITUATION IS REGARDED IN THE EAST; NOTES ON COPPER, SPELTER, TIN, ANTIMONY, FERROMANGANESE, ALUMINUM, AND LEAD.

The effect the war is having on the normal course of trade is clearly shown in the exports of copper. Between August 1 and 14 these amounted to 6058 tons, as compared with 17,518 tons in the same period of last year. Sales of copper go on at around a price level of about 12 to 13c., but the dealers refuse to admit that these establish a daily market price. As a matter of fact there is as much of a market now as there often is in the normal course of business, for the buying of copper is characteristically irregular, and there are often weeks at a time when not enough is being sold to establish a market price. The stopping of quotations is perhaps justified as a war measure, for no one can tell what will happen under such abnormal circumstances, and in a month from now copper may be in fair domestic demand, or it may be impossible to almost give it away. As soon as things steady a little, working quotations for the missing days can be established. Meanwhile the smelters have to hold up their settlements for copper and silver, a not unwelcome necessity. Copper for immediate delivery has been bringing a good premium in London, sales having been made last week at £72 (15⅝c. per pound).

The stocks of copper in England and France were 22,314 tons according to James Lewis & Sons, of Liverpool. Several shippers to Europe will probably divert their copper to the United States, the Braden having already taken that step. The Chile Copper Co., by the way, has had to divert its orders for equipment to the U. S., and the General Electric Co. will proceed to furnish the electrical equipment ordered from the A. E. G. of Berlin. The two companies are allied, so this merely means a shift of contracts from one plant to another.

Several of the other metals are much disturbed also. Spelter has gone up, in the expectation that shipments to England can soon be dispatched, while the former supply of England is likely to be indefinitely interrupted as the chief district is now the battle ground of the contending armies. Tin has gone up, as shipments through the Mediterranean are interrupted. The Chinese tin, which is shipped from Hongkong can easily be sent by way of San Francisco, but it takes some weeks to establish new trade relations, and Straits tin would have a longer journey if sent over the Pacific. Antimony has fallen in price, as it practically all comes to this country by way of England, and the business of forwarding it here has come to a standstill. Platinum is up and is likely to go higher, as the Russian supply may be cut off for a long time. Ferromanganese has almost tripled in price, but as soon as some of the companies here can get one of their stacks running on ferromanganese a plentiful supply will be assured, though at an advanced price, as manganese ores obtainable in Cuba, or elsewhere in our territory, are likely to cost the smelters more than they have been paying. Aluminum is not likely to go very high, as the new plants in the south will greatly add to the domestic supply before the year is out. Lead remains typically unmoved.

Of ordinary mining news there is none. All are standing by their guns to see what will happen. The large companies have given out their reports as usual. Estimating the profits of a copper company is risky business just now, as the first copper made in the beginning of a quarter is only just getting sold at the end of the quarter, and June 30 copper has not reached the market yet.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Juneau

Mine development, power schemes, and mill construction at the Alaska Gold Mines property is going on with good progress. On the 13th or Sheep Creek tunnel level, the full drift, which is 16 ft. wide, is being driven west. The whole face of this drift continues in excellent ore, and is now in a distance of nearly 600 ft. beyond No. 1 shaft. That is to say, this Sheep Creek tunnel, driven primarily to furnish a transportation way from the mine to the mill, and which has already passed through nearly 10,000 ft. of the property, continues to show that the lode at this depth is in place and of good value, as it had previously done at several points in its course. As this tunnel has been driven at an average depth of 2200 ft., as against the previous lowest workings on the Alexander level of 1500 ft., the continued development of ore on this level may, in a sense, be said to have increased the vertical dimensions of the orebody by 50%. At another point, a diamond-drill on one of the upper levels, No. 5, has been prospecting in the hanging wall. At this point, a width of 100 ft. had already been proved, and the drill had passed through 17 ft. additional good ore, with the hole still in ore at the last report.

CALIFORNIA

Amador County

On the occasion of starting the new mill at the Pacific mine at Plymouth, a banquet was held on August 6 at the new hotel. It was quite representative of all interests, and among the guests were W. J. Loring, Albert Burch, James Parks, Fay Chadbourne, Moise Roos-Norman, T. Levaggi, and others. Mr. Loring spoke hopefully of the property, and Mr. Burch promised to aid the people in starting a bank at Plymouth.

Eldorado County

More men have been added to the force at the Rising Hope mine near Placerville. G. W. Englehardt is manager.

Placer County

It is reported that S. P. Soyster, representing Goldfield and Tonopah people, is negotiating with the Placer County Land Co. for 200 acres of dredging land along the Bear river.

Plumas County

An English syndicate has bonded the Arcade mine, near Greenville, from D. McIntyre.——English holders of the Bellevue mine at Gibsonville, and the Farmers' Home mine at Howland Flat, have ordered the temporary suspension of work.——The Scott mine at Seneca is said to be opening well.——Ten men are working two shifts driving an adit 1500 ft. at the Antlered Crest mine near La Porte. The adit is in 400 ft., and it is hoped to open a gravel channel.

Shasta County

(Special Correspondence.)—A new electric hoist, of 2500-ft. capacity, has been installed in the Ohio adit at the Gladstone mine. The mill is treating $10 ore. I. O. Jillson is manager and E. Young superintendent.——The Western Exploration Co. has decided to prospect its Milkmaid properties with a diamond-drill. The plant consists of a 10-stamp mill and four vanners. H. F. Musser is manager.——A number of other properties in the French Gulch field are receiving attention, including the Five Pines, and Washington.——It is reported that heavy shipments of gold-bearing ore from the Reid mine to the Mammoth smelter will soon start. The Reid is in the Old Diggings district, and contains large bodies of low-grade ore. James Sallee is managing owner.——W. W. Feltz and I. Smith, of Redding, are developing a large body of ore containing small shoots of rich quartz, west of that place. They are contemplating erecting a small mill.——The Delta Consolidated Co. has secured patents to its gold-copper claims in the Delta district. A small amount of work is going on. S. D. Furber is superintendent.

Redding, August 16.

The Dry Slide mine has been bonded by A. M. McCarthy to I. Washburn and D. W. McCleum, of Los Angeles, for $25,000. It has been opened by a 1500-ft. adit, and has produced up to 1906 about $400,000.

Sierra County

At the City of Six quartz mine, a new adit is being driven to cut the vein which occurs in a contact of serpentine and porphyry.——The Fruitvale mine was recently examined by Andrew Fitzgerald.——Larger flumes are being constructed for the Brandy City Hydraulic Mining Co.'s gravel property.

Trinity County

(Special Correspondence.)—An examination of the Headlight mine, at Carrville, was made recently by the president, H. W. Miller, and general manager, D. W. Shanks. A small amount of work is under way at the mine, where a large body of sulphide ore is exposed. The Company is still endeavoring to develop a successful metallurgical process. The mine is adjacent to a national forest area, and regulations prevent roasting of the ore.——Driving of No. 6 adit at the Globe Consolidated mine, near Dedrick, continues. The 20-stamp all-sliming mill is running steadily and treating about 120 tons per day. E. E. Harrigan is preparing to install a small mill at the Democrat mine, two miles from Weaverville. The ore is free milling.——The Trinity Consolidated, La Grange, and other hydraulic mining companies are busily preparing for the winter season. Numerous improvements are being made to flumes and pipe-lines, and the great siphons of La Grange are being strengthened to avoid a repetition of last winter's trouble.

Trinity Center, August 16.

The Poverty Slide gravel mine, once worked by hydraulicking, has been bought by the Alta Bert Dredging Co., which will dredge the gravel.——The annual clean-up is under way at the Nash mine.

Tuolumne County

The company owning the Harvard mine is to be sued for $50,000 on account of the death of Giovanni Picatto on October 12, 1913. It is alleged that the stope at 500 ft., where he was working, was dangerous and the compnay was negligent.

COLORADO

Clear Creek County

A 50-ton cyanide plant is to be erected on the Oneida and Stag claims in the Lamartine district.——Operators at various properties, and lessees at the Capital mine are busy, and generally satisfied.

Lake County (Leadville)

Leadville producers of silver and lead are considerably upset over the effect of the war on their products, especially

the former, and the Lake county chapter of the Colorado Metal Mining Association is urging the U. S. Government to buy silver at or about 50c. per oz. The American Smelting & Refining Co.'s local plant is advancing 25c., per oz., the balance to be settled when the market reopens. The new zinc smelter is shut down as there is no market in Europe for the oxide product.

On No. 3 level of No. 1 shaft of the Jonny mine, rich oxidized gold ore was again opened.——Three feet of ore in the Lancaster lease assays 1.44 oz. gold, 219 oz. silver, and 32% lead.

San Miguel County

At Telluride, additions to the Tomboy cyanide plant are well under way. The aerial tramway has greatly lessened the work of hauling the equipment.——The Reinohl process at the Suffolk mill is said to be giving good results. Officials of the Smuggler-Union and Liberty Bell mills have investigated its work.——A new cable was strung on the Alta tramway in a week.

Teller County (Cripple Creek)

The quarterly report of the Doctor-Jack Pot Mining Co. contains the following: Seven groups of lessees during the quarter shipped 2478 tons of $12.29 ore. The Wilson lease is the most important. On Company account was done 345 ft. of work at $4.45 per foot. The ground is very hard at present. Seepage water has been troublesome. Royalties amounted to $3509, and total revenue $3897. The profit was $1245, and cash on hand $59,950, including ore in transit.

The Roosevelt drainage tunnel, which is 7 by 8 ft., with an 18 in. ditch at one side, is being driven at the rate of 6 ft. per day. A cave of ground necessitated driving around the débris, the heading being again in hard ground.

IDAHO

Shoshone County

The Coeur d'Alene district mines produce about 28,000 oz. of silver per day from the lead, zinc, and copper ores, and the action of the U. S. Government in buying silver has resulted in general satisfaction. A few lead producers are doubtful whether work will be profitable under present conditions.

F. A. Heinze and associates have purchased 550,000 shares of the Stewart company held by the Assets Realization Co., thus giving them control of the property, with further opposition of little use.——At the Marsh mine, the raise in the three-compartment vertical shaft, connecting No. 3 level with the main adit, is expected to be finished on September 10. The shaft will be 700 ft. deep. A large double-drum electric hoist is being made by the Nordberg company of Milwaukee. The mill is being remodeled, and a flotation process installed. Ore production will resume in November. Total output is $500,000.

MICHIGAN

Houghton County

The Winona, Hancock, La Salle, and Tamarack copper mines are entirely closed. At the Copper Range Consolidated mines, the Baltic, Champion, and Trimountain, men are working half time, and wages are reduced 10%. Calumet & Hecla expects to work full time underground for another month. About 5000 men, out of the full force of 16,500 in the district, are affected by curtailment of work, and the county is to make a bond issue of $300,000 to help relieve the situation.

MONTANA

Fergus County

The Barnes-King Development Co. has issued a report for the first half of 1914, containing the following remarks by the manager, Geo. T. McGee: Development in the North Moccasin totaled 1567 ft. in ore., and 1781 ft. in waste; also 34 ft. of shaft-sinking and 2272 cu. ft. of skip pockets. The Santiago three-compartment shaft is now used as a main working shaft in place of the one-compartment Barnes-King shaft. No new orebodies were found. Above 400 ft. the ore-shoot is nearly 200 ft. long, with a maximum width of 16 ft. Ore was mainly stoped from west of the old Barnes-King mine bottom levels. The output of 24,435 tons was mined and treated for $4.42, with a profit of $4.20 per ton. At the Piegan-Gloster no further ore development was made, as water-level was reached, and the steam plant cannot cope with it. Tests made on the ore show that a scheme of moderate fine grinding with cyanide solution in Chilean mills, leaching sand and agitation, etc., the slime, is suitable. It is hoped to finish the mill at the end of the year. The surplus is $66,537, against a deficit of $7559 at the end of 1913, but it will take about $75,000 to bring the Piegan-Gloster property to the productive stage.

Missoula County

Owing to the metal situation, work at the Iron Mountain mine and mill at Superior has been curtailed. The plant has only just been overhauled and enlarged. Recent developments have shown 7 ft. of zinc ore in one part of the mine, also 3 ft. of high-grade lead silver ore.

Silverbow County

The Butte & Superior Copper Co.'s report for the second quarter of 1914 contains the following information:

Mine development, feet	4,885
Additions to ore reserves, tons	113,784
Ore treated, tons	95,500
Average zinc content, per cent	18.28
Average silver content, ounces	9.85
Zinc concentrate output, pounds	57,824,296
Average zinc in concentrate, per cent	53.24
Average silver in concentrate, ounces	26.36
Mill recovery, per cent	88.17
Cost of mining, per ton	$ 3.14
Cost of milling, per ton	2.02
Total net value all products	805,866
Operating costs	492,882
Profit, including metal inventories, etc.	372,984

Labor troubles interfered with the tonnage slightly. Metal content of the ore was a little lower, recovery 2.67% lower, costs 29c. lower, and the profit $25,000 lower on taking out the item $60,000 for metal inventories. The latter item represents concentrate not fully settled for.

NEVADA

Esmeralda County

The mining force at the Silver Pick Consolidated has been reduced somewhat, and work concentrated on a winze below 500 ft. Ore in this assays from $18 to $38 per ton over 12 to 6 in. width. Under the new superintendent, Weldon Morris, a new south drift is being driven at 700 ft. in the Oro.

Development in the Jumbo Extension continues satisfactory, and the August output will be about 600 tons of ore. The Company has issued a report covering operations during the 17 months preceding June 1, 1914. In 1913, there was 11,210 tons of ore treated at the Bonnie Claire mill, there being a loss of $17,111. Development totaled 3564 ft., at a cost of $6.28 per foot. Milling cost $3.65 per ton. Cash at the beginning and end of the year was $37,838 and $9350 respectively. The present directors and officers took charge early in 1914. The first five months of the current year show 8653 tons treated at a profit of $53,342. Of this amount, 2418 tons went to smelters. Development totaled 1698 ft., at a cost of $5.72 per foot. Cash on May 31, 1914, was $40,752. It was deemed necessary to purchase the Merger company's Velvet claim, costing $85,000 cash and 171,000 Jumbo Extension shares. Of this, $30,000 has been paid, and $5000 per month until the amount is liquidated. This was a profitable deal in every way. Ore developed on two or more sides is valued at $250,000. An arrangement was made with the Goldfield

Consolidated to treat about 100 tons per day at a cost of $3 per ton, including freight.

EUREKA COUNTY

According to the manager, L. R. Thatcher, the Union Mines Co. is to erect a 50-ton concentrating plant at its mine 35 miles south of Palisade. About 25,000 tons of silver-lead ore has been opened by adits.——The Buckhorn mill is now well up to capacity, with a monthly output of $40,000 of gold.

HUMBOLDT COUNTY

Rochester is active in spite of the war and low price of silver.——Survey of the pipe-line for the new mill is finished, the length being 27,000 ft. A 4-in. pipe will be laid.——High-grade gold ore is being extracted from the Blowback claim on Lincoln hill.——In the lower adit of the Buck and Charley lease silver-lead ore is being opened.——A good ore-shoot has been developed in the Octopus.

LYON COUNTY

The Mason Valley smelter is receiving no more high-grade silver ore for the present. During the week ended August 13 the plant treated 4199 tons of copper ore, 1744 tons from its own mines, 503 tons from the Nevada-Douglas, and 1952 tons from other mines in the district.——The tailing at the old Wheeler mine at Pine Grove has been secured by Ross and Knox, who will concentrate the material and ship the product to the smelter. Pope and Talbot of San Francisco own the property. The lessees will pay a royalty of 50c. per ton, the tailing containing $5 to $6 per ton in gold.——Development at the Constantine copper claims is promising, also at the Silver State and Smith Valley mines.

Some good copper ore has been opened recently in the Casting Copper section of the Nevada-Douglas property, and also in the Ludwig. A carload of 50 tons of ore gives a net profit of $500 over and above mining, freight, and treatment charges. Work on the millsite is under way.

MINERAL COUNTY

(Special Correspondence.)—The Wagner Azurite Co., under management of Frank Everett, is working on the leaching of copper ores. The plan of dry crushing has been abandoned, and material is now crushed wet. Sulphuric acid is obtained from San Francisco. There has been some difficulty in filtering and a hundred blocks of 'Filtros' has been ordered for trial.

Luning, Nevada, Aug. 17.

NYE COUNTY

A great electric storm, not accompanied by rain, interfered considerably with the power lines of the Nevada-California Power Co. last week. Wires between Silver Peak and Millers were down for a day. The storm in the White mountains was severe. In places the large insulators were shot to pieces. Lightning arresters worked well.

Work has been suspended at the MacNamara mine and mill, owing to the state of the silver market. The Company has no great financial resources. Lately the mill has been treating ore for the North Star company, along with some from its own mine.——In July the Tonopah Mining Co. produced 200,015 oz. silver bullion and 101 tons of concentrate, the whole being worth $171,325. The profit was $71,175.——The Extension treated 5636 tons of ore yielding $74,474, with a profit of $28,526.——Several of the companies are storing bullion for the present.——Owing to suspension of work at the MacNamara, Merger, and North Star mines, and interruption to electric power, the district's output last week was 10,464 tons valued at $198,810.

STOREY COUNTY

On account of the war no work is being done at the Ophir and Con. Virginia mines on the Comstock.——At the Yellow Jacket mill 748 tons of dump and 327 tons of mine ore was placed in bins.——The Pumping Association is holding the water below 2500 feet.

WHITE PINE COUNTY

(Special Correspondence.)—The testimony given, at the inquest over the killing of five, and injuring of three, from an accidental and premature explosion of powder, in Eureka Pit, of the Nevada Consolidated Copper Co., on August 4, showed that four men were using a 1-in. water pipe, with a 3-ft. stick driven in the end, tamping. The wooden block, used to gauge the depth of powder in the sprung hole, was in the hole, because the rope attached had become broken. The electric exploders had been placed previous to the accident. The jury rendered a verdict of carelessness on the part of the American foreman in charge of the powder gang. It was a very hot day, and the black powder packed in 25-lb. black iron kegs was exposed to the sun's rays for a long time. The hole had been recently sprung, but was drilled six weeks earlier. It is thought quite probable, from the warmth of the powder and the sprung hole, that sufficient friction may have been generated with the heavy tamping rod to have caused a premature explosion. The Company has since adopted the plan of cooling the powder during hot weather by placing it in a barrel of water.

The Giroux Consolidated mine is shut down temporarily.——The Railroad Valley Co.'s drilling outfit was recently sold to the county commissioners, who are allowed by a recent law to spend $5000 per year in drilling for artesian water on county-owned lands. The first work will be done in the White River valley, two miles northeast of Preston.

Ely, August 11.

During July there were 24 disabling accidents at the Nevada Consolidated mines and works, one being fatal, and the others generally of minor importance. The fatality was at Copper Flat, where a foreigner attempted to board a moving train.——The Consolidated Copper Mines Co.'s mines are shut down.

TENNESSEE

POLK COUNTY

The Tennessee Copper Co. is reducing its copper production by about one-third. This Company is better off than most of

ACID PLANT OF THE TENNESSEE COPPER CO.

the other copper producers, as it makes over 600 tons of sulphuric acid per day from fume at the smelter, and has a steady sale for the product. The acid plant cost $1,905,000.

UTAH

The U. S. Bureau of Mines rescue car No. 2, with J. C. Roberts and John Boardman in charge, has the following itinerary in this state:

Leave Salt Lake City August 15, arrive Sunnyside, August 17 and remain till August 22; then, Hiawatha, August 22 to August 29; Black Hawk, August 31 to September 5; Mohrland, September 5 to September 12; Kenilworth, September 12 to September 19; Standardville, September 19 to September 26; Storrs, September 26 to October 10; Castlegate, October 10 to October 17; Panther, Cameron, and Scofield, October 17 to October 24; Winterquarters, October 24 to October 31; Clear Creek, November 1 to November 7, and reaching Salt Lake City on November 8.

JUAB COUNTY

Among the Knight properties at Tintic the Iron Blossom will be kept open, but the Brooklyn, Rico-Wellington, and Rico-Consolidated in Colorado will be closed. At the Loose properties at Tintic the Gold Chain and Grand Central are shut down. The Gemini, Chief Consolidated, May Day, and Eagle & Blue Bell are still working.——Development is being continued in the Yankee Consolidated. A raise from 1700 ft. has opened 4 oz. silver and 2 to 3% lead ore.——The Mines Operating Co.'s output in July was about 33,000 oz. silver. During the past week, 18 bars weighing 16,000 oz. were sent to the National Copper Bank of Salt Lake City. The metal is 975 fine. There are 100 men employed in the Ontario mine and mill operated by this Company.——The Daly-Judge mine has been closed.

SUMMIT COUNTY

A shipment of ore from the American Flag mine was settled for last week at 1.41 oz. gold, 83.2 oz. silver, 24.7% lead, and 0.77% copper. This was taken from 400 tons of mill ore which had been sent to the stockpile of the Park City mill. This ore averages $15 per ton in gold and silver.——Foundations are in, and machinery for the new hoist and mill of the Daly West mine is arriving at the property. Lessees are still mining ore at 1200 feet.

CANADA

ONTARIO

There will be no curtailment of work at the Nipissing property on account of the silver situation. In July the high and low-grade mills treated 166 and 6700 tons of ore respectively, the refinery producing 415,831 oz. bullion. Prospecting by hydraulicking is still being done. At shaft 73 work on No. 4 level was satisfactory. Beyond the main fault vein 98 is as wide, but lower in value. At 900 ft. vein 64 has been opened for 145 ft., the best part being 24 in. wide, assaying from 12 to 18 oz. per ton. Stoping 2 in. of ore at shaft 63 is yielding 2200-oz. ore. Work at shaft 86 has been stopped as No. 2 level was unprofitable.

The Dome mine produced $82,984 from 17,780 tons of ore in July, the average being $4.19 per ton.——The Hollinger mine produced 16,343 tons of $13.62 ore. Mill recovery was 91% on account of changes in the plant. Costs of mining, milling, and general totaled $4.32 per ton. The gross profit was $132,712, and the surplus amounts to $901,938. Vein 41, cut by diamond-drill, has been opened by a cross-cut at 300 ft., where it is 10 ft. wide and of good value.

KOREA

The Oriental Consolidated mills in June treated 23,932 tons of ore for bullion worth $127,900. A decrease on the May output was expected, while that for July will also be low, as the rainy season is now on. At the Maibong mill, concrete mortar blocks are being put in.

MEXICO

SONORA

Because of the unsettled condition of the copper market, the mines and works at Cananea were to have shut down at the end of last week. This means the discharge of 1900 employees.—There has been some fighting at Quijano in this state between Governor Maytorena and the Colonel P. E. Calles party. Four hundred volunteers left Nogales on August 17 for the scene of trouble.——The Minas Pedrazzini Gold & Silver Mining Co. with mines at Arizpe, held a meeting of stockholders in San Francisco on August 17. A new board of directors was elected, E. L. Dufourcq of New York being president; F. Montijo, San Francisco, vice-president and treasurer; and F. A. Denicke, San Francisco, secretary. The Company hopes to resume work as soon as conditions in Sonora are stable.

PERSONAL

J. C. RAY has gone to Butte.

E. L. DUFOURCQ was at San Francisco.

C. W. PURINGTON is at Bodaibo, Siberia.

W. P. HAMMON has returned from Boston.

F. G. COTTRELL went East from Salt Lake City.

A. E. BOYNTON was in Salt Lake City last week.

F. PETER is in San Francisco from Salt Lake City.

D. C. JACKLING is expected at San Francisco Sunday.

CHARLES JANIN has been at his ranch near Gaviotta.

H. V. WINCHELL went to Tonopah from Salt Lake City.

W. W. MEIN returned from Alaska and has gone to New York.

G. H. CLEVENGER returned from Colorado by way of Salt Lake City last week.

GEORGE I. ADAMS, professor of geology at the Pei Yang University, Tientsin, was married in June.

H. C. HOOVER had expected to leave London for the United States August 13 but has been indefinitely detained.

H. D. MCCASKEY has been called to San Francisco on account of the death of his father, Major General McCaskey.

HERMAN GOODALL of Helena, Montana, has been appointed assayer in charge of the United States assay office at Helena.

KIRBY THOMAS examined properties in Nevada and California after attending the Institute meeting at Salt Lake City.

C. B. LAKENAN has gone East to undergo an operation and H. A. Guess will manage the Nevada Consolidated in his absence.

HENNEN JENNINGS and E. H. BENJAMIN have been in Mariposa county for a few days. Mr. Jennings left for Washington Friday.

J. NELSON NEVIUS of Pasadena, is candidate for state senator from the thirty-sixth district which comprises Pasadena and vicinity.

J. R. BUCHANAN has accepted the position of general superintendent for the Imperial Reduction Co., at Ogilby, Imperial county, California.

MARK LAMB, representative of the Allis-Chalmers company, accompanied by his wife, was at Lima, Peru, recently, and left for Santiago on July 29.

DANIEL GUGGENHEIM, S. R. GUGGENHEIM, and ISAAC GUGGENHEIM, of the American Smelting & Refining Co. are in Europe. When last heard from the former two were in Munich.

M. K. RODGERS and party is touring the West in a motor car visiting the Granby properties at Grand Forks and at Phoenix. From Phoenix they will visit the mines at Hedley, after which they will go to Vancouver en route to Anyox.

Obituary

JACOB LANGELOTH, chairman of the board of directors of the American Metal Company, died suddenly last week of heart disease at his country home in Riverside, Conn. Mr. Langeloth was born in Germany and worry over the war made acute the weakness from which he had suffered for years. He was born in Mannheim, and after engaging in the metal business for several years was sent here 27 years ago by the German parent of the American house to found the American Metal Co. Since then his business influence had grown until he was a director in many important concerns, among them being the Balbach Smelting & Refining Co., the Corn Exchange Bank, the General Development Co., the Metallurgical Company of America, the Mexican Bank of Commerce and Industry, the Miami Copper Co., and the Wetherill Separating Company.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, August 20.

Antimony	No quotes
Electrolytic copper	15¼
Pig lead	3.90
Quicksilver (flask)	No quotes
Tin	" "
Spelter	7¾
Zinc dust, 100-kg. zinc-lined cases	No quotes

There have been some sales at the above prices. While there is practically little doing in quicksilver, the price remains at $85 per flask, although it is reported that 50 flasks were sold at $90 each early in the week. The New Jersey Zinc Co. is to make zinc dust, which should relieve the situation later on. Stocks are low, and quotations are around 15c. per pound.

EASTERN METAL MARKET.

(By wire from New York.)

NEW YORK, August 20.—Lead is quiet at 3.85 to 3.90c., spelter strong at 5.55 to 5.65c., while the copper market is still at a standstill. There have been small copper sales, but no quotations. The copper companies are supporting the market. The Granby Consolidated company of British Columbia has passed its regular quarterly dividend of $1.50 per share. The Federal Mining & Smelting Co. has reduced the quarterly dividend on preferred stock from $1.50 to $1 per share.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Aug. 13	No quotes	July 8	56.12
" 14	" "	" 15	55.60
" 15	" "	" 22	54.14
" 16 Sunday		" 29	53.42
" 17	" "	Aug. 5	No quotes
" 18	" "	" 12	" "
" 19	" "	" 19	" "

May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

There is still no regular quotation for silver in New York, and this will continue indefinitely, any prices arranged being only by special sales, or requirements of the United States Mints. Smelters in Utah settled for the metal up to August 11 at 52c. per oz., and from that date until the market is regular, only 25c. per oz. will be paid as part payment. Writing on July 30, Samuel Montagu & Co. state that stocks of the metal in London were low, and there was an absence of speculative commitments, with a small amount of business. On July 24 an Indian currency return showed an increase in the holding of silver rupees (1 rupee = 30 cents).

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending

COPPER

Exports of copper for the week ended August 13 totaled 1846 tons, a decrease of 6253 tons. Since January 1 the total is 255,568 tons, an increase of 23,294 tons compared with 1913. There have been sales of electrolytic in London at £72 per ton, or 15⅝c. per pound. This was for immediate delivery. Standard was quoted nominally at £59 15s. to £60 15s. for spot and three months' deliveries respectively.

The following yields (in pounds) for July have been declared by the respective companies, compared with those for June:

Mine.	July.	June.
Arizona Copper	3,300,000	3,742,000
Braden	1,332,000	662,000
Calumet & Arizona	5,940,000	5,862,300

Utah Copper	.....	13,268,106

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
July 16	37.50	July 30	37.50
" 23	37.50	Aug. 13	85.00
		" 20	No quotes

Monthly averages.

June	5.00	4.84	Dec.	5.07	....

Joplin, Missouri, zinc people expect a rise in this metal, as Europe supplies 66% of the world's total, this being cut off for the present.

TIN

The tin situation seems to be easier, as prices in New York, which were up to 65c., have dropped to 50c. per pound.

CYANIDE

There is little to add to last week's notes on this salt. Stocks are low, and the price is 25c. per pound. Roessler & Hasslacher are able to take care of all contracts in force, but cannot supply the entire American demand. They hope soon to receive a large supply by way of Belgium. The cyanamid company of Niagara Falls probably will be unable to supply any cyanide whatever.

Midyear Spelter Statistics

By C. E. SIEBENTHAL

Figures compiled by the United States Geological Survey, from reports by all zinc smelters operating during the first six months of 1914 show that the production of spelter from domestic ore in that period was 171,496 short tons and from foreign ore 3562 short tons, a total production of 175,058 tons, compared with 166,463 tons for the last half of 1913 and 180,213 tons for the first half. The spelter made in Illinois increased about 9000 tons, that made in Kansas declined about 8000 tons, and that made in Oklahoma increased about 5000 tons, compared with the quantities of spelter made in those states during the last six months of 1913. The stock of spelter held at smelters on June 30, 1914, was 64,039 tons, against 40,659 tons at the beginning of the year and 21,856 tons at the middle of 1913.

Zinc ore imported	19,994	11,422	9,052
Zinc content	9,204	4,293	2,949
Zinc ore exported	9,745	7,968	8,042

From the foregoing figures and the records of the Bureau of Foreign and Domestic Commerce it is calculated that the apparent consumption for the period was 149,363 tons, which, compared with 132,387 tons for the last half of 1913 and 153,073 tons for the first half, seems not much below the normal.

The imports of spelter were 506 short tons, compared with 567 tons during the last half of 1913 and 5533 tons during the first half. The exports of spelter of domestic origin were 773 tons, against 1168 tons in the last half of 1913 and 6615 tons in the first half. The exports of spelter of foreign origin, including spelter exported from bonded warehouse, as well as articles manufactured from spelter of foreign origin and exported with benefit of drawback, were 2048 tons, compared with 4672 tons in the last half of 1913, and 8724 tons in the first half. The imports of zinc dust were 1272 tons, of which 269 tons came from Australia.

The imports of zinc ore were 9052 short tons, containing 2949 tons of zinc, compared with 11,422 tons of ore, containing 4293 tons of zinc, in the last half of 1913, and 19,994 tons of ore, containing 9204 tons of zinc, in the first half. Of the imports of zinc in ore in 1914, about three-fourths came from Canada. The exports of domestic zinc ore were 8042 tons, compared with 7968 tons in the last half of 1913 and 9745 tons in the first half.

The price of spelter at St. Louis started at 5.125c. and rose to a maximum of 5.35c. on February 4 and 5. A gradual decline, followed by a sharp break in April, brought the price down to 4.875c. on April 28. A slight recovery was again followed by a decline, and the period closed with spelter at 4.825c. per lb. The average St. Louis price for the first half of the year was 5.1c. The London price of spelter opened at £21 10s. a long ton (4.648c. per lb.) and reached the highest point in the latter part of January, at £21 12s. 6d. a long ton (4.675c. per lb.). The price was nearly stationary for the next five months, closing the period at the same figure at which it began, £21 10s. a long ton (4.648c. per lb.). The minimum price of the year, £21 5s. a long ton (4.594c. per lb.), prevailing during the latter part of June, was less than one-tenth of a cent below the highest price of the year.

At the average St. Louis price for the first six months of 1914 the value of the spelter from domestic ore was $17,492,592, and the value of the total output from both domestic and foreign ores was $17,855,916, compared with $17,608,402 and $17,645,078 for the last half of 1913 and with $20,193,930 and $21,265,134 for the first half of 1913.

COMPANY REPORTS

ORSK GOLDFIELDS, LIMITED

The dredging property operated by this Company is in the Orenburg district, Southern Urals, Russia, and the report is for the year to January 31, 1914. The Kolchan dredge worked from May 8 to November 13, 1913, handling 382,800 cu. yd. for £29,727. The Pokrovsky dredge worked from June 28 to November 13, 1913, handling 117,500 cu. yd. for £15,464. Tributers recovered £3740. The total gold yield was £48,933. Operating costs were £10,314, and the working profit was £36,533. Winter upkeep of the boats, royalty, etc., reduced this to £18,373. Depreciation and loan interest left a net profit of £680. During the current year the boats started on April 30 and 28, respectively. During June 1914 the two dredges treated 102,400 cu. yd. for £5311, and tributers £3316. Generally considered, the result for 1914 will be about the same as the previous term.

MOUNT MORGAN GOLD MINING COMPANY, LTD.

The financial year of this Australian company ended on May 31, 1914, and the annual meeting was held on July 17. The reports of the directors; general manager, B. Magnus; mines superintendent, A. A. Boyd; and works superintendent, J. W. Moule, contain the following information:

Work from the 363 to 950-ft. level totaled 4630 ft., of which only 17 ft. was at the lowest point. Lately the cost of development has been 68c. per ton of ore mined, compared with 24c. in normal times. Ore reserves amount to 1,211,000 tons of high grade, and 1,914,000 tons of low-grade copper material. A large amount of preparatory work was done during the year, and it was necessary to send concentrating ore to the smelter in preparing this ore for stoping. Conveyor-belts have proved a success in handling filling from the open-cut, and their use is to be extended underground. The fire in the Many Peaks property is under control. The smelter treated 303,428 tons of ore, including 60,075 tons of basic ore from the Many Peaks mine, yielding 18,957,120 lb. of copper and 102,848 oz. gold. Total revenue was £956,542; working costs, £3 per ton; expenditure, £680,190; surplus, £276,352; balance from 1912, £121,298; total available balance, £397,650; depreciation, maintenance, experiments, etc., £77,297; four divi

dends, £200,000; and surplus for current year, £120,353. Another dividend of £50,000 was paid on July 1. The reserve, contingent, insurance, and undivided profits total £360,989.

At the Company's coal mine the shaft is down 245 ft., and a tramway 4½ miles long is to be constructed.

ASSOCIATED GOLD MINES OF WESTERN AUSTRALIA, LIMITED

At Kalgoorlie, Western Australia, this Company owns 52 acres of mining property. The output to date is 1,514,953 tons of ore yielding 970,767 oz. gold worth £3,516,537, and £728,000 in dividends. Results during the past few years have been poor, those for 1913 showing 127,856 tons for £152,105, and £24,764 in dividends. The report of the general manager, D. F. McAulay, shows that development totaled 3959 ft., of which 1419 ft. was in unprofitable ground, and 316 ft. in ore over $4.80 per ton, the width of profitable ore being 63 in. There is nothing of value below No. 19 level, but there remains a large area of promising ground from that point to the surface. Malcolm Maclaren examined the mine during the year. It is impossible to estimate ore reserves in set quantities. Broken ore in reserve was 33,306 tons averaging $5.40 per ton. The dry-crushing, roasting, and cyanide plant treated 350 tons per day, averaging 3.78% sulphur, with 93.35% recovery. The bullion output was 35,804 oz. gold and 197 oz. silver.

SURFACE EQUIPMENT OF ASSOCIATED MINE, KALGOORLIE.

Costs were as follows: mine development, 50c.; mining, $1.82; treatment, $2.66; general, 17c.; insurance, 5c.; and disposal of bullion, 3c.; a total of $5.23. Development cost $16.70 per foot. Wages were increased somewhat, also fuel advanced 6c. per ton. The turbo-generator was stopped, and the Kalgoorlie Power & Lighting Corporation now supplies power for motors. Steam power cost $1.04 per ton of ore treated.

The Associated company is developing the Keeley and North Thompson mines near Porcupine, Ontario.

ZINC CORPORATION, LIMITED

This Company buys zinc-bearing tailing from certain mines at Broken Hill, New South Wales, and treats it by flotation methods; also, operates the South Blocks mine and mill. The flotation plant treated a total of 350,120 tons, including some from the Company's own mine, yielding 102,850 tons of zinc concentrate averaging 44.2% zinc, 12.5% lead, and 12.1 oz. silver per ton. This was further separated into 81,830 tons of zinc concentrate assaying 47.1% zinc, 7.7% lead, and 10.5 oz. silver; and 12,623 tons of lead concentrate containing 55.4% lead, 15.4% zinc, and 31.8 oz. silver. The Horwood selective flotation process produced 4580 tons of concentrate, which will treat 3442 tons of by-product slime from the zinc plant. The Horwood and Lyster processes are a success. The South Blocks mill treated 162,956 tons of ore, yielding 30,680 tons of concentrates assaying 66.2% lead, 6.4% zinc, and 9.27 oz. silver; and 36,536 tons of zinc tailing containing 15.6% zinc, 5.1% lead, and 1.9 oz. silver, which was sent to the flotation plant. Total revenue was £628,505, and profit £187,681, from which the preferential, and preference and ordinary shares received dividends of 20 and 30% respectively. The mine's reserves amount to 971,784 tons of 14.8% lead, 9.5% zinc, and 2.4 oz. silver ore.

MINING DECISIONS

UNFENCED SHAFTS—OWNERS NOT LIABLE FOR INJURIES

In a state where there is no legal requirement that shafts or pits upon mining claims be enclosed, the owner of live stock which have fallen into such unfenced shafts or pits while straying on the public domain, cannot recover damages for their loss against the owner of the mining claim.

Strong *v.* Brown (Idaho), 140 Pacific, 773. April 15, 1914.

MINING CONTRACT—SALE OF ALL MINERALS CONSTRUED

A contract of sale of all the oil, gas, coal, sulphur, and other minerals in and under a described tract, that may be found by drilling and mining operations which may be conducted on the land, is a valid contract of sale, which the purchaser may not destroy by failing to drill or mine. As between the purchasers the contract is joint and several, and each is liable for the contract price, and the vendor may sue all or any number for such price.

Whited *v.* Johnson (Texas), 167 Southwestern, 812. June 17, 1914.

LEASED MINE—LIABILITY OF OWNER

One who performed work on and furnished materials which benefited a mine, cannot recover from the owner on the theory of an implied contract, because the owner acquiesced in the furnishing of work and material where the mine was rented to a third person, and the owner could not object; but if the owner encouraged the doing of the work and the furnishing of material, or allowed it without objection, knowing that plaintiff was looking to him for payment, there is an implied contract.

Reynolds *v.* Norman (Colorado), 141 Pacific, 466. June 1, 1914.

LEASED MINE—WHEN NOT SUBJECT TO LIENS

The mere relation of lessor and lessee, where the lessee has an option to purchase, is not of itself sufficient to subject the lessor's interest in the property to a lien on a contract for materials furnished at the instance of the lessee. It must also appear that at the time the material was furnished, there was a mutual understanding that it was to be used in the improvement of the particular property to which a lien is sought to be attached therefor, and that the lessor knew that the materials so furnished were used or to be used for such purpose.

Milwaukee Gold Mining Co. *v.* Tompkins-Christy Hardware Co. (Colorado), 141 Pacific, 527.

FOREIGN MINING CORPORATIONS—ASSESSMENT WORK

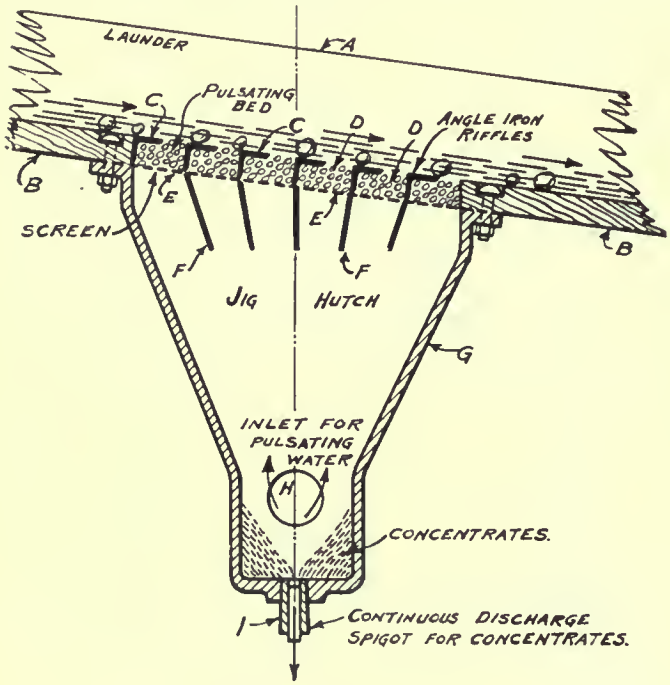
Where, under a state statute, a foreign corporation is required to file copies of its articles of incorporation, and designate a state agent before it can hold title to real estate, conveyances of mining claims to such a corporation prior to its filing such articles are invalid and vest no title. While an affidavit as to performance of annual assessment work is *prima facie* evidence of such performance, it is by no means conclusive and may be rebutted by a counter-showing that $100 worth of work was not done. Not even a showing that $100 was actually expended for that purpose is sufficient. There must be proof that the work was actually done and not merely paid for.

Dickens-West Mining Co. *v.* Crescent Mining & Milling Co. (Idaho), 141 Pacific, 566. June 2, 1914.

New Machines and Devices

The Richards Pulsator Riffle

The Richards pulsator riffle is the result of the application of an intermittent pulsating current of water to the Hungarian riffle, which will be recalled as that angle iron shaped riffle which has been so largely adopted in the working of placer deposits with sluice-boxes and also used on gold-saving tables on dredges. The riffle consists of a series of standard angle irons usually 1¼ by 1¼ in. to 2½ by 2½ in., which are spaced at various distances, depending upon the character and amount of gravel to be treated. One leg of the angle is at right angles with the bottom of the sluice and the other leg is parallel with the bottom of the sluice. The present riffle with automatic discharge is obtained by apply-



LAUNDER WITH PULSATOR RIFFLE.

ing the pulsating current, which is the underlying principle of the Richards pulsator jig. The water pressure required is 7 lb., equivalent to a head of 16 ft. The quantity of water required is approximately 40 gal. per minute per sq. ft. of riffle surface. The only adjustment is the water-supply, which is controlled by an ordinary globe or gate valve in the water pipe.

The construction and operation of the pulsator riffle will be understood by reference to the accompanying diagram, where *A* is a suitable launder; *B*, bottom of launders; *C*, common angle iron riffles; *D*, openings between the angle iron riffles which may be ⅜ in., ¼ in., or ⅛ in., depending upon the size of gravel to be treated; *E*, a screen preferably of brass with openings to allow the passage of fine gold or mineral; *F*, guide plates inside of the jig hutch; *G*, the jig hutch which together with the guide plates is fastened to the under side of the launder or tables and under the screen; *H* is the inlet for the pulsating water current from the Richards pulsator valve; *I* is the spigot at the bottom of the jig hutch for discharging the gold particles or mineral concentrate. It is said that the riffle will not pack and therefore requires no clean-up, and has many other advantages over the Hungarian riffle. This device is made by the Denver Engineering Works Co., of Denver.

Commercial Paragraphs

Fort Wayne Electric Works of General Electric Co., recently published Bulletin No. 46203, which is devoted to single-phase watthour meters. The type K5 meter shown in this bulletin has several features novel to this type.

The B. F. Goodrich Co., Akron, Ohio, is manufacturing a rubber bucket that will stand alone. The bucket holds 2½ gal. water and when not in use folds up to about ½ inch in thickness. It has a strainer spout with no springs or metal parts.

Eberbach & Son Co., Ann Arbor, Michigan, has recently placed upon the market a recording jolly spiral spring balance. The balance was devised by Edward H. Kraus, of the University of Michigan, and is claimed to be especially well adapted for the rapid and accurate determination of the specific gravity of solids such as minerals, rocks, and coals.

National Tube Co., Pittsburgh, Pennsylvania, has for distribution the second edition of Bulletin No. 134, which contains a large amount of information regarding the various types of N. T. C. iron body and brass mounted wedge gate valves. The bulletin is fully illustrated with both halftones and line drawings showing details of construction and operation.

Busch-Sulzer Bros.-Diesel Engine Co., of St. Louis, with Pacific Coast agency in the Rialto building, San Francisco, California, will be pleased to distribute reprints of an address by Mr. Diesel before the American Society of Mechanical Engineers on 'The Present Status of the Diesel Engine in Europe' and a few reminiscences of the pioneer work in America.

The Terry Steam Turbine Co., Hartford, Connecticut, announces the appointment of Fidanque Bros. & Sons, of New York and Panama, with main office at 15 Whitehall street, New York, as representative for the Republic of Panama and the Canal Zone. The Cleveland office of this Company has been moved from 710 New England building to 503 Union building.

The Maas patent drill-hole compass, for which E. E. White of Ishpeming, Michigan, is agent, it is claimed can be used in the survey of drill-holes for both direction and inclination to a depth of 3000 ft. The compass is placed in a thermos bottle or glass tube with hot liquid gelatin and lowered in a water-tight phosphor-bronze case with a tube containing hydrofluoric acid. When the gelatin is cold the rods are removed and readings taken.

The Lunkenheimer Co., Cincinnati, Ohio, has recently issued a brochure entitled, 'Grinding,' in which the subject of grinding as applied to valves is fully described and illustrated. Many years ago, before it was realized that the life of a valve could be prolonged by regrinding when the seating surface was worn, a valve that was not tight or as near as was possible to make it, was replaced with a new one. The expense was considerable and created a great deal of dissatisfaction. Valves furnished with seating surfaces which are capable of being reground have resulted, and it is to this subject of regrinding valves that this little brochure is devoted.

SILVER is reported to have been sold in considerable quantities in New York, August 22, at 56 cents per ounce, that price being determined by a London quotation made August 21, the first 'official' quotation since the war opened.

FORTY-NINERS and their immediate successors will recall the 'Miner's Ten Commandments' mentioned in our letter from Angels, but to many they will be new. This early decalogue was written by James M. Hutchings and was first published in the *Placerville Herald* in 1853. It is a characteristic expression of the humor and philosophy of the men who dug gold from the sunny gravel beds of the new Eldorado and is well worthy of preservation. Last year Mr. Charles E. Hewes, of Murphy, California, sent us a copy which we are glad to reproduce in connection with the account of the Loring dinner.

CONFUSION has arisen because of identity of names, between Mr. James A. Barr, manager of the phosphate rock department of the International Agricultural Corporation and living at Mt. Pleasant, Tennessee, and the Mr. James A. Barr who is chief of the Convention Bureau of the Panama-Pacific Exposition. The Mr. Barr who lives in Tennessee, and will be remembered as the author of 'Testing for Metallurgical Processes,' a highly useful little book, has no intention of leaving his regular professional work even to father conventions at San Francisco; an important bit of work that the other Mr. Barr is performing admirably.

PASSAGE of the act permitting transfer to American register of American owned foreign boats may help to relieve the ocean freight situation, but is at best a makeshift. Our whole system of navigation laws must be rewritten if we are to compete for the carrying trade of the world. In such minor matters as boiler inspection we are placed at a serious disadvantage without any apparent corresponding increase in safety, and back of it all is the fundamental fact that American men and money are in normal times worth more on the land than the sea. Such problems are not to be hastily solved by emergency legislation, though even a little help in such times as the present is welcome. If ownership rather than flag be the test, the American merchant marine is now third, if not second.

WITH the gradual readjustment of market conditions many of the mines which suspended operations with the beginning of hostilities in Europe are again producing. Reports from Idaho and Utah are extremely optimistic and the production of silver, lead, and zinc is again almost normal. While the copper situation has not been determined, the position of zinc has been strengthened and lead and silver are in a much better position than they were ten days ago.

CYANIDE conditions in the United States are still bad and it is not yet apparent from whence an adequate supply of the salt is to come. The plant at Perth Amboy is running full capacity but is hardly likely to be able to carry the full load, besides which the supply of raw materials may become difficult. Large shipments of cyanide ordered by various firms shortly before the outbreak of the war may still come through, and while the excess carbon and calcium carbide will interfere with the use of cyanamid, it may still be possible to use that salt, of which there is an abundant supply, in special situations. It happens that arrangements were under way to manufacture cyanide from cyanamid when the war broke out. The right to use the necessary patents had been secured and the machinery was in Berlin ready for shipment. It is just possible that it may still come through. However, for the present there is a sufficient supply, and care and forethought may be depended upon to make the best of the situation. It is hardly likely that the shortage will, in the end, be as serious as was at first feared.

GRINDING pans, except in Australia, have not received the attention that they merit as machines for the part or complete reduction of ores preliminary to cyaniding or other treatment. The real merits of the pan were brought out at Kalgoorlie, where a large number are in operation in stage crushing of ores or sliming pulp and are giving every satisfaction. Pans are used in Broken Hill, where the object is not to slime the blende and galena, but to grind it preliminary to further concentration. A few metallurgists in other parts of the world have studied pans, and have found them to give good results; but while somewhat surprised at their work in Australia, others have held to the belief that the tube-mill is the right machine for fine grinding. During the past year there have been several articles

and discussions on grinding pans in the *Press,* which have attracted wide attention. One of the most interesting of the different types of pans in use is the Freeman, devised at the Great Fingall mine, Western Australia, and in favor also at the Sons of Gwalia, Lake View & Star, and other mines. It is of the standard size of five feet diameter, and about 30 inches deep, provided with dies on the inside bottom, and shoes on a revolving gear-driven muller. The speed is necessarily adjusted from experience with any particular ore, but between 50 and 60 revolutions per minute is generally desirable. The pan is centre-fed and has a classifying action, centrifugal force throwing the heavier and larger particles to the outside. About half way up one side of the body a three-inch pipe is fitted, this extending half way to the centre of the pan, ending with a short bend. The function of this pipe is to take off pulp of the grade desired. Particles of ore travel inward as they decrease in size, finally reaching the proper part of the pan for discharge. The pipe may, of course, be arranged to take the pulp at any point across from the periphery to the muller yoke; this depending on what grade of material is required. So far, in Western Australia, the Freeman pan has been used in stage crushing such as the following: five 1200-pound stamps crushing a fairly hard ore through about six to eight-mesh screens (a duty of 8.47 tons per stamp day in 1913), the pulp flowing to one Freeman pan, which only allows one product to escape by the pipe classifier. This product goes to Wilfley tables, is further classified, and the coarse material is finally ground in tube-mills with more concentration. As an intermediate grinder, such as described, this pan does excellent work. Shoes and dies last only from 20 to 30 days; but considering the work done, this is not excessive. The cost of preliminary grinding at the Lake View & Star mill in 1913 was 18 cents per ton of ore milled, stamping being 31 cents and tube-milling the same. An investigation into the working of this pan may prove beneficial to millmen in this country.

BUTTE AND LEAD—A CONTRAST

Most interesting comparisons and contrasts are suggested by the accounts of the hearings of the Commission on Industrial Relations at Lead, South Dakota, and Butte, Montana. In the one district no man can obtain employment from the principal company, the Homestake Gold Mining Company, unless he signs an agreement not to belong to the labor union; at Butte he cannot work for the Anaconda Copper Company unless he can show a union card. What the Commission thought of Lead after studying the situation was summed up by one of its members, Mr. John R. Commons, in the following well deserved compliment paid Mr. T. J. Grier, the manager:

"You have here the most remarkable business organization that I have ever come across in this country. You have developed welfare features which are beyond anything that I know of, and they are given with a liberal hand. You have a high scale of wages and reasonable hours—very fair hours. There has been evidently great progress made in taking care of the employees in the hospital service, and you have taken care of the cost of living, have kept it down below what employees in other communities have been forced to pay. You have practically been able by your great strength here as a huge corporation, dominating the whole community, to look out for the welfare of your employees, and to bring in an admirable class of citizens. It seems also that you are influential in politics, that you secure a good class of officials and that you have secured the enforcement of law, the reduction of immorality. It seems also that you make an effort to build up the religious life of the community and that your policy is broad and liberal in all respects. I take it also, that this policy depends solely upon your personality. Such inquiries as I have made here indicate that in all cases the stockholders leave all these matters to you personally, and that this broad policy has been carried out by you on your own initiative, and that you have felt that it was necessary, for the good of the community, the securing a fine class of labor here, which you have undoubtedly done, that you should hold the reins pretty tight on this community."

At first the Commission was inclined to blame the companies both at Lead and Butte for requiring seven days work per week, but its members soon satisfied themselves that this was at the wish of the men and involved no real hardship. The hospital service, costing the men the same amount at both places, was found to be superior at Lead, in that not only the men but their families are cared for, there is a medical inspection service, and all physical ailments are treated. At Butte tuberculosis is reported to be prevalent among the miners and is not treated by the hospital doctors, though the Company is spending large sums of money to improve ventilation and other working conditions.

At Butte, as is well known, the companies and the Western Federation of Miners have operated under a closed-shop agreement that became practically an alliance. Wages have been paid on a sliding scale governed by the price of copper, but the unworkable character of the contract is shown by the fact that, while since the system was started the companies have increased wages when copper was high, they have not, in general, decreased them when the price of metal went down, except for long periods. On the other hand, the men complain that the present wage scale represents an increase of but 7 per cent in 36 years, while in the meantime the plumbers, carpenters, and other workmen at Butte have increased wages to more than twice as much per day as the miners. The agreement between the union and the companies at Butte has secured to the latter a steady supply of laborers, while operations elsewhere have been interrupted by strikes, and the workmen of Butte have constituted an unfailing source of supply for funds

wherewith to finance strikes called by the Western Federation in other districts. Despite repeated failures, these assessments were kept up until the Butte miners rose in a spectacular revolt and drove out the officials of the Federation. A new local union of 6000 or 7000 men, has been formed and it apparently dominates the situation. There have been various charges and counter charges, and public sympathy with the new organization has been modified by the fact that among its leaders, if not dominant in it, are men who are of I. W. W. affiliations. Among the charges brought out in the recent hearing was the one that the old Butte Miners Union was really dominated by the Anaconda company and that it was impossible for the men in general to control its course because of the dominance of a corrupt ring which was in turn dominated by the Company. Evidently the mine operators in Butte can find little cause for self-congratulation in having profited for a time by a course of action which gave them peace though it worked to the disadvantage of operators elsewhere. Evidently, also, the excellent results achieved at Lead are to be largely ascribed to Mr. Grier as an individual. The two cases reinforce the old observation that a benevolent absolutism gives the best government when the right man is in charge, while the most democratic form of government does not secure good conditions when control falls into the hands of a small ring concerned mainly with self-advancement. Our own sympathies are with the system of trade agreements, though we would not want to recommend any agreement with the Western Federation as we have known it. Mine operators, we believe, are not adverse to dealing with unions; indeed, at Homestake the men are organized, but they have been unfortunate in having had to deal with a union dominated by men and methods that cannot be defended.

In conclusion, lest we be misunderstood, let us reiterate our own views. It is a fundamental right of workingmen to organize to further their own interests. The modern employer is a powerful aggregation of units, in dealing with which the individual employee is at a disadvantage. In dealing with a corporate employer, the employees should be able to represent themselves as an aggregate body, so that there may be some parity between the forces involved. The specifying by a mining company that no man may be employed by it unless he be a member of such an organization, though undoubtedly legal, is as contrary to social justice as the specifying that no member of any organization will be employed, or the refusing to recognize any employee as representing anyone or anything except himself as an individual. The right line of action is that followed by the management of the Homestake mine in encouraging its employees to form an organization, officered by respectworthy men, that might adequately represent them in dealing with their corporate employer. Individual workers in dealing with million-dollar corporations are no more effective than painted warriors on a beach shaking spears at a visiting battleship. It has now been clearly established that great corporations are not above the law; when it is equally clearly established that organizations of workingmen are also not above the law a long step will have been taken toward the quieting of the present social interest.

THE STATE GEOLOGISTS

The excellent practice of getting together in the field is receiving a further impetus this week in a meeting of the American Association of State Geologists in the Lake Superior country. The party was to assemble at Houghton, Michigan, on Thursday and to see the copper country under the competent guidance of Messrs. L. L. Hubbard and W. E. Hopper. The Michigan iron ranges were later to be inspected with Messrs. C. K. Leith and E. E. White as guides, and finally Mr. F. B. Taylor is to explain the glacial geology about Mackinac Island and St. Ignace. Next Tuesday the state geologists will join the members of the Lake Superior Institute of Mining Engineers in a trip by special steamer to Detroit. Last year, it will be recalled, the Association made a similar excursion along the Mississippi south of St. Louis, examining critical exposures in Missouri and Illinois. Such field conferences smooth out many a controversy, and it would be good economy for every state to require its official geologist to attend each meeting. The Association is finding a constantly increasing field of usefulness. It was the outgrowth of an earlier and smaller body called the Mississippi Valley Association of State Geologists, which was organized at a conference held at the Quadrangle Club in Chicago early in 1906. The director of the then newly created State Geological Survey of Illinois, when entering on his duties, felt the need of the advice of his more experienced confreres, and invited them to lunch. Then, there being more than three Americans together, there resulted a president, vice-president, and secretary, and so the Association was born. Later this gave place to the larger organization, which has formed a convenient medium for conference not only between state geologists, but as between them and the officers of the United States Geological Survey. It has mainly considered problems of administration and methods of work, but the later disposition to take up matters of correlation and nomenclature is to be commended, since, without disposition to criticise the excellent work of the United States Geological Survey, it may fairly be said that it is good for the country and for the science of geology in America, to develop a strong and independent body of opinion on professional matters. The great majority of the American states maintain geological surveys of some sort. They differ in character, duties, and strength, but all are concerned with applying geology to public uses and mining men will save themselves much useless work if they will become familiar with what the state geologist has already learned, when they undertake investigations in new territory.

As It Looks in London

By T. A. RICKARD

*The statement made by Sir Edward Grey on Monday was a superb expression of Great Britain's attitude and prepared us for the inevitable ultimatum to Germany, whose brutal violation of Belgian neutrality left this country no possible course but to respond to the Belgian appeal. Last night England declared war. Personally, I hate the necessity for participating in this organized murder, I deplore the reversion to barbarism, and the destruction to civilized ways of living, but this country can do nothing else. And as it must be done, let it be well done.

My chauffeur is a military reservist; last night he was called to arms; I have offered my car to the Government. It may be of use in expediting the movements of officers. Our Mining Club was animated today by the discussion of means for organizing a volunteer corps. Undoubtedly a considerable number of professional mining men will offer their services, and it is thought desirable that they should be in the same company.

Just now we are hearing more of the distress among tourists than of the horrors of the battlefield. However, it is no laughing matter. This happens to be the height of the tourist season, and the number of Americans stranded in London is astonishing. Their troubles call for sympathy, but they are fortunate as compared with those that were unable to escape from the arena of warfare. I have met two or three men who were among the last to cross France or Germany in an effort to reach London, and the stories they tell suggest that those who are still there must be in a sad plight. H. C. Hoover, Edgar Rickard, and other friends of ours have taken organized measures to furnish assistance. As the banks are closed until Friday, it is next to impossible to get currency or to cash letters of credit. Meanwhile, the army of belated travelers is increased by the withdrawal of several steamers previously announced as sailing tomorrow, Friday, or Saturday. One man who had engaged a $5000 suite of rooms on a crack liner has been glad to get a berth in the second-class of the *Virginian*, scheduled to leave for Canada on Friday. R. W. Brock, Deputy Minister for Mines, for Canada, deems himself lucky to have a second-class berth on the same steamer. The prompt action of the New York bankers and the President in sending $1,500,000 and the cruiser *Tennessee* will be intensely appreciated. It is estimated that 80,000 Americans are stranded in Europe, of whom fully 30,000 are in London. One of them, anyway, has volunteered in Britain's cause. Another tells me that the Germans will soon be throwing bombs into London, so, on my advice, he is going to the Cornish coast for safety, the granite cliffs on that side of the island offering an inhospitable aspect to an enemy.

Meanwhile, the temper of the people is fine. The soldiers going to mobilization are cheered, but there is no frothy vaporing of words. "England expects that every man this day will do his duty." Nelson's message lives yet and rings in the ears of his countrymen, from the Jack tar to Sir John Jellicoe, appointed yesterday to the supreme command of the home fleets. This appointment, and that of Sir John French to the military command, have given general satisfaction. It is a sad coincidence that two other Johns, both known in their time as 'Honest John,' have resigned from the cabinet. I refer to Lord Morley and Mr. John Burns. They disagreed with the policy of Mr. Asquith and his coadjutors. And these two worthy men represent the small but thoughtful minority unalterably opposed to war. They are pacifists of the impracticable type, like your Mr. Bryan.

August 5, 1914.

The Institution of Mining and Metallurgy has called for volunteers, and the War Office has expressed its appreciation of this offer. On the first day after the circular was issued by the secretary, over 150 enlisted, and among them are three well known Anglo-American engineers: J. Power Hutchins, Peter Nissen, and C. S Herzig. To be accurate, Mr. Nissen is a Canadian, but he is regarded here as one of the clever and energetic American group of technical men.

A friend of mine present in the House of Commons on Thursday afternoon tells me that Asquith's statement of the diplomatic negotiations immediately preceding the rupture was intensively impressive. With his white hair, his clear-cut features, and beautiful enunciation, he told the story quietly, without any expression of rancor, and the House listened in dead silence until he came to the proposal made by Germany that England should betray France and acquiesce in the violation of Belgian neutrality, on the promise that she herself would not be molested. When he called that "an infamous proposal" there was a response that showed that all parties were of one mind. As the Prime Minister said: We are fighting to "fulfill a solemn international obligation—an obligation which, if it had been entered into between private persons in the ordinary concerns of life, would have been regarded as an obligation not only of law but of honor, which no self-respecting man could possibly have repudiated." We are fighting also to "vindicate the principle that small nationalities are not to be crushed, in defiance of international good faith, by the arbitrary will of a strong and overmastering power."

August 7.

*In this and succeeding letters, the *Press* will print extracts from Mr. Rickard's personal letters from London, believing that an account of the war as seen by a mining man in that great centre will be of interest to mining men everywhere. Mr. Rickard is an Englishman who was born in Italy, passed his early boyhood in Russia, managed mines in France and Australia, and lived in the United States more than twenty years. His sympathies are naturally with the Allies, but he will endeavor to be as impartial as he may.

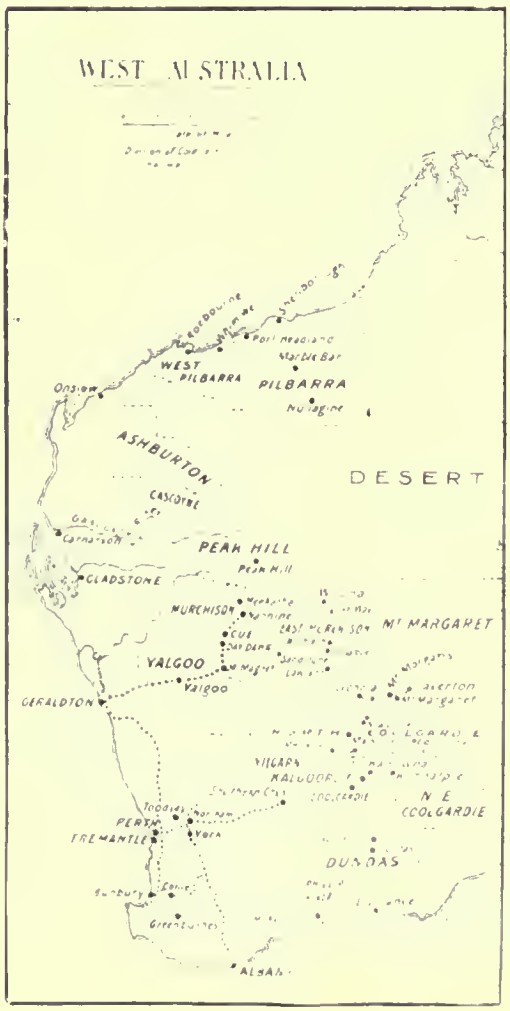
CAMEL TRAIN ON THE ROAD TO MARBLE BAR, WESTERN AUSTRALIA.

Northwestern Australia and Its Mineral Resources

By A. W. ALLEN

The Pilbarra and West Pilbarra goldfields, in the 'Nor' West' of Australia, account for some 50,000 of the million or so square miles covered by the western state. The 'Nor' West' occupies an intermediate position between the moister areas farther north and the more temperate regions farther south. Of natural beauty it has little or none, and the scarcity of vegetation makes a breeze in summer, which in similar latitudes elsewhere might be refreshing and welcome, seem like the blast from a furnace. In winter the climate leaves little to be desired, although the lack of water and almost entire absence of vegetation gives the country an uninviting aspect. Rain occurs in periodic downpours of short duration and over a very limited season. The only trees of any kind are found near the river beds or alongside water courses. There is no running water in this part of the state, but artesian bores are proving the fact that water is obtainable at depth, and this circumstance will tend to foster a pastoral industry which has hitherto suffered considerably from the effects of drought.

The Pilbarra fields are not without historical interest, since the district was among the earliest to produce gold, and mining was carried on for several years before the Coolgardie and Kalgoorlie fields were developed. The isolated position of the 'Nor' West,' the problem of transport, and the depressing summer climate, all contributed to delay its development. The chief township, Marble Bar, is situated some 75 miles from the nearest port, and, until recently, transport from the capital of the state was by means of steamer from Fremantle to Port Hedland and from thence inland by coach or other conveyance. The country is exceptionally flat, but there are long stretches of sandy waste which make locomotion by any means a tedious business. Of late a railway has been built from Port Hedland to various small townships inland, but in the earlier days the difficulties of transport were, in a measure, overcome by the use of camels. These animals are well able to stand the rigors of an arid region, and although slow in movement, they are able to manage, under pack load, a much longer stretch at one time than either the horse or mule. The camel 'pad,' generally off the main road, makes an ideal



COONGAN RIVER, MARBLE BAR DISTRICT, WESTERN AUSTRALIA.

cycle track. The camels are owned and driven by Afghans whose repugnance, based on religious scruples, to anything in the nature of pork is well known; and they not only refuse to touch it, but will not allow their camels to carry it. In an instance which came under my notice a party of prospectors inland ordered a side of bacon from Port Hedland and gave detailed instructions that it should be packed in the centre of a bag of flour so as to escape detection by the Afghans. They had not calculated on the prevailing temperature, however, and a spot of grease showing on the side of the sack aroused the suspicions of the Afghans when they were several days out. A jack-knife applied to the sack soon turned suspicion into proof and the whole cargo was immediately dumped alongside the road. The Afghans and their camels then returned to Port Hedland, and successfully disclaimed any responsibility in connection with the loss to the prospectors.

In climate the 'Nor' West' is certainly a district of extremes. The air is abnormally dry and a water bag is a constant companion, night or day. Luckily it works ideally in such a climate so that a cool drink is always available. When rain comes it makes up for lost time in a few minutes, and as much as 30 inches has been recorded in one shower. From December to March the district is visited by severe cyclones, the township of Port Hedland being in a belt of hurricanes which extends across Australia and occasionally play havoc at Townsville, on the east coast of Queensland. On such occasions a wind velocity of 120 miles per hour has been recorded; and in the earlier days at Port Hedland, before the houses were as substantially built as they are at present, it was customary to ensure against the removal of one's dwelling from one street to another at such times by the simple precaution of a chain stretched over the roof, which was affixed to a 'dead man' on each side of the house.

In a district where the atmosphere is entirely devoid of moisture for long stretches and where there is no shade to cool the air, the temperature may rise to an almost unbelievable figure. For obvious reasons I refrain from giving my own experiences or quoting the readings which I took from time to time of maximum shade temperature. I may say that the district held the palm, according to official reports, for the greatest number of consecutive days on which the shade temperature exceeded 100°F. During the season dealt with the number of such days in succession was 64. At such time the country is invaded with swarms of flies, similar to the common house flies. These little vermin positively attack one in their endeavors to get at any part of the face from which moisture may be sucked. So persistent are their efforts in this direction that they have literally to be wiped off. Fly nets attached to the hat are sometimes worn, but their adoption leads to much discomfort, and results in a feeling of suffocation to the wearer. As

an alternative to the net a number of corks are sometimes seen attached by small pieces of string to the brim of the hat. By perpetually wobbling the head the flies may be prevented from settling. This is a last resource, however.

Local timber is used for fuel and mining purposes, but it is exceedingly scarce. The smaller 'mulga,' which is almost a scrub, is available, together with a small amount of eucalyptus. These woods are of high calorific value, but in view of scarcity are expensive for any purpose. There is little grass in the 'Nor' West' and feed for horses is almost exclusively confined to compressed fodder which is brought up, at great expense, from the south. Spinifex grass is to be found and the tired traveler who thinks it might form a comfortable cushion will be galvanized into new life if he uses it for the purpose. The spiny points have no difficulty in piercing the ordinary habiliments, and of going still further if given the least provocation.

Indigenous animal life is found in the emu, kangaroo, and dingoe. There are also quantities of the smaller varieties of the 'possum. Immense areas in the 'Nor' West' are used for sheep raising, but water is scarce and feed is of poor quality.

As a result of almost insurmountable difficulties mining has languished. Rich patches of auriferous quartz have been found in all parts, but the veins can only be worked when they carry high metal content. Operations are mostly confined to the oxidized zones, and several promising properties were dropped as soon as these were passed and a drop in recovery was indicated in following the simplest methods of treatment. The average yield from the Pilbarra field has been in the neighborhood of 2 oz. gold per ton milled, and from this fact may be surmised expense of treatment and the difficulties of working generally.

In addition to gold, the 'Nor' West' possesses other mineral possibilities. There are immense iron deposits which in other places and in proximity to coal would be of considerable value. As it is they can hardly be called an asset. Copper is found throughout the field, and West Pilbarra contributes a large proportion of the output of this metal from the state. On the other hand, the general distribution of the metal throughout the 'Nor' West' has constituted one of the most serious drawbacks to simple cyanidation of the gold ores. Tantalum and asbestos are also found in small quantities, but the latter is too short a fibre, as yet, to be a commercially important asset.

At Nullagine an auriferous conglomerate, similar to the Rand banket, is in evidence. A mill was erected in the later nineties to treat this, but the yield proved too small to justify the continuance of operations.

Throughout the district there occurs iron stained seams of jasper. In places this approximates agate jasper in appearance and characteristics.

COPPIN'S GAP, MARBLE BAR DISTRICT, WESTERN AUSTRALIA.

Rejuvenating the Chloridizing Roast

By F. SOMMER SCHMIDT

At the Park City plant of the Mines Operating Co. the ore is delivered from the mine to a bin above the crusher, from which it discharges into a trommel with 1 and 1½-in. openings. The undersize passes through a revolving dryer, where the moisture is reduced to about 5%. The oversize of the trommel falls on a picking belt, where mine wood and waste are removed. It then passes through a No. 5 Gates gyratory crusher and, joining the dryer fines, is elevated to the crushed ore-bins of 400 tons capacity. Sections of this same bin are used for salt and coal. From these bins a mixture in the required proportions is delivered to the rolls, where it is crushed to ⅜ in. It is then elevated to the mix-bins above the roasters. The present scale of operations is about 150 tons per day, and all the crushing is done in 8 hours.

Roasting Department

There are 8 shaft roasters of the intermittent type, 10 by 10 ft. inside, and one continuous Holt-Dern roaster. The walls are reinforced concrete, 10 in. thick. There is a wood grate about two feet from the bottom, supporting a layer of coarse crushed rock. The space below the grate forms an air chamber. The grate supports the charge and distributes the air blast.

In starting the roaster, a mixture of one ton of coal-dust dampened with oil is spread over the gravel floor of the roaster and ignited. This is followed by a special mixture of ore, salt, and coal, richer in coal than the charge. The blast is then turned on and the roasting begins. When the layer is burning properly the air is cut off and a regular charge of 5 tons is added and spread by hand. When the roast has burned through this charge, a second charge of about 10 tons is added, and about 4 hours later a final charge of the same amount is added. This brings the total charge up to about 7 ft., which will roast through in from 8 to 12 hours.

When the roasting zone has reached the surface at all points, the air blast is shut off. The discharge door is opened and the hot roasted ore is sluiced out with mill solution under a 45-ft. head through a 1⅛-in. nozzle. The numerous small steam explosions makes it necessary to direct the stream with a rod from one side of the furnace. It takes from one to three hours to sluice out a roaster charge of 24 tons.

The new continuous Holt-Dern roaster has been in continuous operation for 6 months. The column of ore moves down as the roasting zone rises. The air blast travels in an opposite direction to the ore. The air blast coming in contact with the roasted ore becomes highly heated. It then passes through the roasting zone where combustion is taking place, whence it passes to the layer of moist unroasted ore above. It leaves the furnace cool and free from dust. Whatever loss there is in the process is due to the coarseness of the ore protecting the minerals from the chloridizing action of the furnace. It has been proved that this can be largely overcome by finer grinding.

Leaching Department

The sluiced roaster product passes to the leaching tanks. There are 6 of these 20 by 12-ft. tanks, having a capacity of about 135 tons each. In the bottom of each tank is a 12-in. round discharge hole for discharging the tailing. This is closed by a wooden plug having a 4 by 4-in. stem extending to the top of the tank. It is surrounded by a boxing provided at intervals with 12 by 12-in. sluice gates to regulate the rate of discharge. Four lines of 4-in. drain tile are laid in the bottom of the tank and cemented in position. This tile system connects at one end of the tank with a 3-in. wood pipe solution line. This line leads the solutions either to the silver tank or the weak-solution tank, depending upon the content. The weak-solution tank is used for further sluicing, while the silver tank solution is pumped over the precipitators.

The solution from the silver tank is first passed over the silver precipitator. This is an inclined cement runway covered with copper wire of various diameters and of short lengths. The silver and the small amount of gold is precipitated as a sponge which parts clean from the copper by simple agitation with brooms, the loosened silver being caught by a clean-up settling tank below. This precipitator reduces about 90% of the silver present in the solution. From the silver precipitator the solutions are passed through the iron boxes, which are similar to the zinc boxes of a cyanide mill. Here the solution, coming in contact with scrap iron, deposits the remaining silver, all the copper, and some of the lead. From these iron boxes the solution passes into the barren sump free from silver, gold, and copper.

Precipitating the Silver

The silver precipitate is allowed to settle in the clean-up tank, whence it is sluiced out into the filter-boxes and washed and dried. The silver in the precipitate is probably in the form of an oxide with some chloride and is in a rather flocculent form. In the bullion furnace impurities are slagged off and the silver obtained is in bright bars running 975 fine. The copper precipitate is cleaned from the iron with brushes, and when washed and dried is shipped in that form.

The object of the roast is to convert the metallic compounds to chlorides, in which form they are leachable. For this purpose common salt is added to the ore, forming about 8% of the charge. The amount of chlorine liberated depends not merely upon the amount of salt

added, but also upon the composition of the ore which causes the reactions. Thus the presence of sulphides and manganese in the ore is a great help to the chloridizing action. The reactions that take place in the furnace depend also upon the physical conditions such as fineness, moisture, and intensity of heat in the roast zone. The fuel is coal culm and forms about 2% of the mixture. This makes a very cheap fuel, costing only $1.96 per ton of fuel at the plant.

Acid Manufacture

There is no condensing tower at the plant at present, but should one be built the saving in cost of acid would be considerable. The cost of acid at present is about $1000 per month, and it would not be unreasonable to expect a saving of nearly all this amount if sulphide ores are available. The plant has actually run for months in the past on a more sulphurous ore without buying any acid. The presence of lime is not desirable, though small percentages can be handled. It uses up acid, but if there is enough sulphide present it may furnish sufficient sulphuric acid to compensate.

The mill solution that is used for leaching contains about 5 lb. of sulphuric acid per ton. There is also hydrochloric acid present, but this is a by-product of the leaching of the roasted mixture. No hydrochloric acid is added at any stage of the process. The main features of the process are chloridizing roast, sulphuric acid leaching, and precipitation on metallic copper and iron. The main improvements are in the roasting department and the favorable results are due to the following causes: The temperature of roasting is well controlled. The mixture is well disseminated and the mechanical features of grate bars, air chambers, and air blast, added to the proper composition of the charge, all conspire to give good results. The moisture in the ore is also a very important item, and this is carefully controlled at the dryer to give 5 per cent.

Types of Furnace

Of the two types of roasters in use at the plant, the new Holt-Dern type is the better, being an outgrowth of the old shaft type. It is continuous in operation, the roasting operation not being interrupted by either the feeding or tapping. There are movable grate bars operated by eccentrics. At regular intervals the mechanism is set in motion and the charge lowered a foot or two. The roasted product dropping out below is sluiced to one of the tanks. More charge is added at the top. The old type of furnace, on which all the present cost data given in this article were obtained, is completely shut down at the end of a roast and is entirely sluiced out. It requires the attention of several men in starting and also in sluicing and is completely shut down in starting and stopping and allowed to cool of necessity. The greater economy in the cost of operating this new furnace is apparent on slightest inspection. Added to this economy is the greater saving due to the fact that this furnace will handle a finer product which is amenable to chloridizing to a higher degree. The old type has been saving 78% of the silver and the Holt-Dern furnace will probably save over 90% with 10-mesh material. The extraction of the silver when once chloridized can be figured as 100 per cent.

About 50% of the present gold value is saved. More can be saved by adding lime chloride to the leaching tanks at a cost of 25c. per ton of ore, but as the present tailing is running just about that in value, the saving is not worth going after. Only a small amount of lead is saved, but there is only a small amount present. The saving could be increased by electrolytic precipitation if the return justified.

There is very little copper in the ore, but probably over 90% is saved. The Mines Operating Co. made a series of extraction tests on the small Holt-Dern furnace for a period of 5 weeks. The feed was the same as is at present employed in the mill, the coarseness being ⅜ in. For the period the extraction of silver made in the shaft type was 80.3, while with the H.-D. furnace it was 86.4. The percentage of salt in both types was 7.5 of the weight of the ore.

The advantages which this type of furnace has over other types are: No measurable volatilization loss of valuable metals; no dust loss; product is well adapted to leaching and sluicing, even when the ore contains considerable slime; requires only a low percentage of cheap fuel; high recovery without fine crushing; the roaster gases are cool and concentrated and easily condensed for leaching purposes.

The Holt-Dern Roaster

The Holt-Dern roaster is a new type of roaster introducing a number of attractive features, and the tests which have just been completed show that the furnace works as well metallurgically as it does mechanically. My investigations of the plant covered a little over a month's time, involving a trial run of 1500 tons. The data presented, I think, can be considered representative. This trial lasted 31 hours and treated 9.6 tons of ore crushed to pass a ¼-in. opening. The furnace is a small one, being constructed for the purpose of trying out the mechanical features. These have proved successful, and larger furnaces are now being designed.

Considering that the ore consists of stope fillings of the Ontario mine, its value runs surprisingly uniform, varying from 8 to 11 oz. silver from day to day. The ore is well adapted to chlorination with the exception of insufficient sulphur and occasional days of high lime, but is not adapted to any other process. The composition of the ore used in this test can be considered representative of the usual heads. The analysis is:

Ag, 9.52 oz.; Au, 0.029 oz.; Pb, 0.71%; Cu, 0.11%; SiO, 79.4%; insoluble, 83.9%; Zn, 0.57%; S, 1%; Fe, 7.9%; Mn, 0.89%; CaO, 1.20 per cent.

The silver is present partly as chloride and as a constituent of the galena and zinc-blende and tetrahedrite. The iron is mainly oxide and little pyrite. The manganese is in pyrolusite and CaO as limestone.

The composition of the 'mix' used was as follows:

	Per cent.	Figured without moisture.
Dry crude ore	83.4	87.2
Moisture	4.4	...
Salt	8.3	8.7
Coal dust	2.3	2.4
Pyrite, 70% pure	1.6	1.7
	100.0	100.0

This mix was roasted in the usual way, and the analysis of the product is as follows:

Au, 0.025 oz.; Ag, 9 oz.; Pb, 0.72%; Cu, 0.13%; SiO, 72.2%; insoluble, 75.8%; Zn, 0.95%; S, 0.7%; Fe, 7.3%; Mn, 0.93%; CaO, 0.73 per cent.

The silver is present as chloride, the gold one-half as trichloride, the lead as sulphate and chloride, the copper as oxide and chloride, the zinc as oxide and sulphate and chloride, the iron as oxide. The reduction in the CaO as shown by comparison between the crude and the roasted mix is possibly due to formation of insoluble silicate.

Loss of Weight in Roasting

From results obtained in an experimental roaster, it has been determined that the loss of weight sustained by the mix in roasting averages about 7%. The loss may be said to be the loss of weight of the coal, moisture, and one-half the salt. The percentage of sulphur is not much of an item. Using the factor of 93% of the weight and calculating the analysis from the crude heads for comparison with the above, we have:

Au, 0.027 oz.; Ag, 8.89 oz.; Pb, 0.67%; Cu, 0.11%; SiO, 74.5%; insoluble, 78.6%; Zn, 0.54%; Fe, 7.4%; Mn, 0.84%; and CaO. The sulphur naturally suffers reduction by volatilization.

It will be seen from this that there is no measurable volatilization of the silver or gold. As a further check, if the assumption is made that the SiO_2 is constant in weight, the relation of SiO_2 to Ag should remain constant with no volatilization. This calculation shows that in the crude ore 1 oz. silver corresponds to 8.34% SiO_2, while in the roasted mix 1 oz. silver corresponds to 8.20% SiO_2, which would indicate an actual increase in Ag, the error being due to cumulative inaccuracies and proving that there is no perceptible volatilization of the silver.

In order to determine the uniformity of the roast, 100-lb. samples were taken every 4 hours by cutting the discharge stream. Small samples of each of these were kept separate and a 24-hour leaching test was then made.

For this purpose 500 gm., without any further crushing, was leached in a percolator with solution leaving the iron boxes before regeneration with H_2SO_4. This solution has practically no free acid while there is a shortage of pyrite in the ore. The mill has run for months without adding any H_2SO_4 to this solution while there was pyrite available, but at present about 5 lb. per ton is being added.

Laboratory Tests

For the laboratory tests, in order to cut the mill practice time down from 48 to 24 hours, the amount of H_2SO_4 added was 10 lb. per ton. The solution contains about 27% NaCl. The temperature of solutions was about 62°C. In all the following leaching tests the extraction can be calculated direct on the roasted mixture to zero volatilization. Experiments were made to determine the loss in weight of the roasted mixture in leaching, and the results are as follows:

	Loss, %.
60-lb. sample	12.2
50-lb. sample	13.3
1000-oz. sample	12.0
	12.5

This average is 12.5, which can be checked by the comparison of the SiO_2 percentage in the roasted mix 72.2 and the leached tailing 83.2 giving a loss in weight of 13.2 per cent.

Extraction Test on Interval Samples

Interval.	Roasted mix, assay Ag.	Leached tail., assay Ag.	Extraction, %.
1	8.0	0.8	91.2
2	8.2	0.8	91.4
3	8.0	0.7	92.3
4	8.4	0.8	91.6
5	10.6	0.8	93.4
6	10.0	0.8	93.0
7	8.6	0.6	93.0
8	9.5	0.8	92.6
9	10.2	0.9	92.2
	9.06	0.78	92.4

These results show the extraction to be high and uniform and agree closely with numerous other tests as shown in the following.

Influence of Size of Particle

To obtain data on the best size for crushing, screen tests were:

Screen Test on Raw Mix

Size, mesh.	Weight, %.	Assay, Ag oz.	Value, %.
On 8	34.2	6.8	28.0
14	24.1	8.0	23.3
20	12.6	8.0	12.1
40	12.3	9.0	13.4
60	7.3	10.8	9.5
Through 60	9.5	12.0	13.8
	100.0	8.3	100.0
Composite		8.2	

Screen Test on the Roasted Mix

Size, mesh.	Weight, %.	Assay, Ag oz.	Value, %.
On 8	41.2	6.9	31.2
14	20.8	8.0	18.3
20	10.3	10.0	11.3
40	13.3	12.4	18.1
60	9.0	13.2	12.9
Through 60	5.4	13.6	8.1
	100.0	9.1	99.9

It will be noted that in the roasting the coarser sizes

have increased at the expense of the fine material. This is what would be expected from an inspection of the roasted product and is a very desirable result as an aid to subsequent leaching.

A leaching test was made on each one of these sizes separately, under conditions described above, to determine which size gave the best extraction.

LEACHING TEST OF SIZED PRODUCTS OF ROASTED MIX

Size, mesh.	Assay of tails., Ag oz.	Value, %.	Extraction, %.
On 8	0.80	45.9	89.8
14	0.80	23.2	91.2
20	0.60	8.6	94.7
40	0.60	11.1	95.7
60	0.60	7.5	96.0
Through 60	0.50	3.7	96.7
	0.72	100.0	92.3

It will be seen that while the fine sizes give the best extraction, the extraction on the coarser sizes is really higher than would have been expected.

A leaching test was made in a suitable filter-box to determine the relative velocity of leaching of the different sizes by interrupting the leaching action and making a screen test on the imperfect tailing. For this purpose the ordinary mill solution containing 22% NaCl and 5 lb. H_2SO_4 was used on a 60-lb. sample, leaching for 48 hours, but using only three times the weight of solution as compared to ore, instead of the usual mill practice of 6 solution to 1 of ore.

SCREEN TEST OF IMPERFECT TAILING

Size, mesh.	Ag assay.	Weight, %.	Value, %.	Extraction, %.
On 8	1.60	41.0	39.8	79.7
14	1.40	20.1	17.0	84.7
20	1.40	9.7	8.2	87.7
40	1.20	10.6	7.7	91.7
60	1.80	8.8	9.6	88.1
Through 60	3.00	9.7	17.6	80.7
	1.65	99.9	99.9	84.1
Composite	1.60			

These sizes were then leached separately for 24 hours, passing through 3 times the weight of solution to 1 of ore, making by this time a total of 6 solution to 1 of ore. The screening separation made at this stage of the leaching will not give the same results as if made after complete leaching, as shown in the following, and as this determines the percentage of value, this column must be considered with qualifications for the present.

LEACHING TEST ON SIZED PRODUCTS IMPERFECT TAILING

Size, mesh.	Ag assay.	Weight, %.	Value, %.	Extraction, %.
On 8	1.00	41.0	48.0	87.3
14	0.80	20.1	18.8	91.2
20	0.80	9.7	9.2	93.0
40	0.80	10.6	9.9	94.4
60	0.60	8.8	6.2	96.0
Through 60	0.70	9.7	7.9	95.5
	0.85	99.9	100.0	91.8

It will be noted that in the first stage of the leaching the coarser products were leached down to 1.8%, while the fine material still retains a value of 3.0%. The second leaching reduced the value of all sizes, but mainly the fine, which apparently resists the leaching most. This is logical and could have been predicted, but that the percentage of extraction on the coarser sizes should be so high is rather surprising. While the fine gives the highest per cent extraction, the difference is not enough to make good the expense of crushing finer and handling fine material in the mill.

One of the advantages of this roaster is the comparative ease with which it is possible to get an excellent physical constitution of the roasted ore for subsequent leaching. The gathering of fine material in roasting and its release only as the metal is leached out is well shown in the following experiment, in which 40 lb. was leached with the mill solution for 48 hours, duplicating mill conditions as nearly as possible:

A SCREEN TEST OF THE TAILING—PERFECT LEACH

Size, mesh.	Ag assay.	Weight, %.	Value, %.	Extraction, %.
On 8	0.80	36.8	38.0	89.8
14	0.60	22.2	17.1	93.4
20	1.00	9.1	11.8	91.2
40	0.80	10.1	10.4	94.4
60	0.80	6.3	6.5	94.7
Through 60	0.80	15.5	16.1	94.8
	0.77	100.0	99.9	92.6

The percentage of value in the fine in this test, 16.1, does not check that in the interrupted leaching test, and this discrepancy is not without reason. It will be seen that the percentage weight is the controlling factor in the distribution of value. In the crude ore mix the per cent of fine is 9.5; in the roasted mix, this is reduced to 5.4, showing the effect of gathering the fine particles. In the partly leached ore, some of the fine has been freed to the extent of 9.7%, while in the thoroughly leached mix it has been increased to 15.5%, thus containing 16.1% of the value of the metals.

An analysis of the tailing gave the following: Au, 0.005 oz.; Ag, 0.75 oz.; Pb, 0.41%; Cu, 0.06%; SiO, 83.2%; insoluble, 88.1%; Zn, 0.8%; S, 0.2%; Fe, 4.5%; Mn, 0.62%; CaO, 0.52%; chlorine, none.

The gold and silver are present as metallics or included in undecomposed sulphides; the Cu as silicate and undecomposed tetrahedrite; the Pb and Zn as sulphate; the Mn as oxide; and the CaO as sulphate.

It will be seen from the low tenor of copper in this ore that it is extremely difficult to get sufficiently accurate determinations for close figures on extraction, but it may be said that operations on Cu ores of better defined content gave extractions between 90 and 95% of the copper.

The mill solutions contain 8 lb. of metallic lead per ton, the profitable extraction of which has not yet been worked out. The lead is in the form of chloride. When removed from solution, more of the lead takes its place as far as the capacity of the mill solutions for containing this Pb compound permits.

While this ore is not in the least refractory to chlorination, there is no reason why more complicated ores cannot be treated to good advantage with this furnace, and it is my opinion that with a cheap and highly efficient chloridizing roaster of this kind the big field will be in the treatment of copper ores.

Any furnace that can make a chloridizing roast to yield an extraction of 92% and do this at a cost of 24c. per ton in a 10-ton unit, and do this for 16½c. per ton in a 35-ton unit, has to be reckoned as a valuable development in the field of metallurgy.

Cost Data

The following is a comparison of the cost of operating the two types of furnaces, but does not include salt, which item will probably be a little less in the H.-D. than in the shaft type:

Cost per Ton of Ore Roasted

	Shaft type.	H.-D.
Labor	$0.380	$0.054
Power	0.049	0.045
Repairs	0.026	0.020
Starting oil	0.038	.....
Coal-dust	0.046	0.046
Total	$0.539	$0.165

The great item in the saving is in the labor. In the new furnace one roaster man and one sluice man can handle 200 tons where with the present furnaces it requires 3 men and 2 sluicers.

Cost Data for Typical Month with Present Equipment
(Tonnage treated, 4356)

Department.		Total.	Per cent of total.	Remodeled.
Crushing:				
Labor	$0.083			
Power	0.020			
Supplies	0.050	$0.153	7.0	$0.153
Drying:				
Labor	$0.029			
Power	0.013			
Coal, etc.	0.050	0.092	4.0	0.092
Rolling and Mixing:				
Labor	$0.114

General expense		0.357	16.0	0.357[4]
		$2.242	100.0	$1.869

[1]Finer grinding. [2]Saving in labor, starting oil, repairs. [3]Saving in half the acid estimated. [4]Includes royalty but not depreciation.

In the cost data quoted the improved conditions referred to mean finer crushing, to 10 mesh, employment of H.-D. roasters, employment of condensing tower for making acid which is now being bought, and access to bodies of sulphide ore.

The cost of crushing is high, due to the fact that this is part of the old Ontario mill equipment. The dryer is an old one of poor design and is too small for the work.

Grade of Ore That May Be Treated

Determination of no-profit grade of ore under present and hypothetical conditions:

Under present conditions the mining cost will be assumed as $1.40, silver figured at 55c. an ounce, and the copper, lead, and gold recovered pay for the marketing of the silver.

With the present plant and present ore, the no-profit grade is, with an extraction of 78%, 8.7 ounces.

With the improved plant, finer grinding, H.-D. roasters making half the acid used and paying royalty, the no-profit grade is, with an extraction of 90%, 6.60 ounces.

With improved plant as per above, eliminating royalty of 17.1c. per ton, the milling cost would be $1.698, the no-profit grade, with an extraction of 90%, 6.26 ounces.

Auto-traction drill rigs are said to give satisfactory service and are coming into more general use. One of these machines was recently used by an Eastern contractor in excavating rock on a power-house contract, near Turner's falls, on the Connecticut river. The work consisted in drilling 30-ft. holes in a broken sandstone formation, 10 ft. apart. The machine had a 5-in. cylinder, 8½-in. stroke, and a 10-ft. run. Four or five holes per day were put down with this outfit, the best day's work being 210 ft., or seven 30-ft. holes in 10 hours' time, according to the Sullivan Machinery Co. of Chicago. On an adjoining contract, in similar formation, the average work done with churn or well drills of the ordinary type was two holes per day. Of course, the churn-drill holes were larger in diameter, permitting the use of a larger quantity of powder in the bottom of the hole; but excellent blasting effects were secured with the auto-traction drill-holes by springing or chambering the hole before the final blast was exploded.

Gold output of mines in the Dutch East Indies in 1913 was as follows: Ketahoen (Sumatra), $166,000; Paleleh (Celebes), $346,000; Redjang Lebong (Sumatra), $970,000; Simau (Sumatra), $840,000; and Totok (Celebes), $221,000; a total of $2,543,000, against $2,760,000. A dividend of 15% was paid by the Redjang Lebong, and 20% by the Simau. Tin output of the islands of Banka and Billiton was 17,345 tons, compared with 17,202 tons in 1912. Coal output of the government mines at Ombilien (Sumatra) was 411,082 tons. A coal mine has been purchased by the government of the Indies in southeast Borneo containing 147,000,000 tons.

The Plymouth Mill, Amador County, California

By AN OCCASIONAL CONTRIBUTOR

HEAD-FRAME AND ORE-BINS.

On August 1 the new 30-stamp mill of the Plymouth Consolidated Gold Mines, Ltd., was placed in operation and has been running continuously ever since.

Ore from the mine is hoisted to a two-story hopper, the upper part being used for waste, and the lower for ore. From the latter the ore is fed to a No. 5 Gates gyratory crusher, the discharge of which falls on an 18-in. belt-conveyor which conveys the ore for a distance of 630 ft. to the top of the mill. The maximum slope of the conveyor is 21 15′. Another conveyor distributes the ore over the 1400-ton bin by means of a traveling tripper. The mill is situated at the top of a hill which affords ample mill head and storage for the tailing.

From the orebin, the ore is fed by a Challenge machine to 30 stamps of 1250 lb. weight. The stamps are crushing to ¼-in. size, and so far have given a duty of 14 tons per stamp per 24 hours, which capacity can be easily increased. Only 20 stamps are being used at present, 10 being kept in reserve. This makes it possible to make repairs to the stamps without curtailing the crushing capacity of the mill.

The discharge of all the stamps goes to a distributing box and automatic sampler, from where the coarse material is fed by Caldecott cones and settling cones to two 8 ft. by 22-in. Hardinge mills. The overflow of the cone and the discharge of the mills flows to 10 amalgamating plates 6 by 12 ft. in size. The plate tailing passes through amalgam traps, and is elevated by a 36-ft. bucket-elevator to a sloughing-off cone. The overflow of the cone goes to the slime vanners, and the discharge of the cone passes over a Richard hindering-settling classifier which feeds two No. 6 Wilfley tables. The overflow of the classifier goes to the coarse vanners.

There are 30 Isbell vanners in the plant. Six of them work on fine sand, and 24 work on slime. The Wilfley tables are handling about 35 tons each. The feed to the vanners is automatically distributed by a series of distributing barrels, which cause an equal feed to all vanners, even when some of these are cut out for repairs.

Quicksilver is fed to the Hardinge mills, in which about 66% of the total amalgamation takes place. Most of the amalgam remains in the Hardinge mill forming a coating of amalgam in between the pebbles, and this amalgam can be easily removed without emptying the Hardinge mills.

All the clean-ups of the mill, and the middling of the Wilfley table are returned to the Hardinge mills, and it is possible also to return the coarse tailing of the Wilfley for regrinding whenever this is warranted by the grade of the ore.

This combination of stamps and Hardinge yields a product 90% of which will pass a 40-mesh screen, and the production of slime and colloidal matter appears to be considerably less than is the case in the other Mother Lode plants, where the ore is crushed directly through a fine screen. The plant is crushing now approximately 300 tons per day, but its ultimate capacity is about 350 tons.

On August 15 the first part clean-up was made, giving satisfactory results. The metallurgical efficiency of the plant and other more specific data are not yet available, but the assay of the tailings indicate a satisfactory recovery. A detailed account of this mill, accompanied by plans and photographs, will be published in the *Press* later on. The Plymouth is one of the famous old mines of the Mother Lode which, after lying idle a number of years, was recently reopened through the efforts of Bewick, Moreing & Company.

GENERAL VIEW OF THE MILL.

A Study in Applied Geology

By C. A. STEWART

While it is generally conceded that in the important and hazardous task of estimating the value of the unexplored part of an orebody geological investigation is indispensible, only those engineers especially trained in geology appreciate the steps by which a geologist reaches his conclusions. When the old but ever-new question, 'What will it do in depth?' arises, owners and prospective investors are wont to summon an expert, propound to him the problem, and accept his answer with a blind faith, the completeness of which depends upon the expert's reputation or the questioner's disposition.

As a matter of fact, all such geological prophesying can go no further than a statement of the probabilities, and it is often impossible to convey in the summary of a geological report an idea of just how probable is this or that conclusion. Only by following the reasoning of the geologist as embodied in the whole report, noting the limitations under which his observations were made, and comprehending his qualifying statements and the reasons therefor, can a man appreciate fully the significance of a geologist's attempt to prophesy. Because mining men sometimes refuse to make this detailed study of a geological report, and insist upon a bare 'yes' or 'no' when 'it is probable' or 'it is not probable' is the only feasible answer, the geologist often receives unwarranted criticism.

In this article I propose to trace step by step the process of reasoning by which certain conclusions were reached in one specific problem, which is typical of those daily confronting mining geologists. I hope to indicate something of the possibilities as well as the limitations of geological work, and to show how details of apparent unimportance actually have great weight; how 'theoretical questions' are frequently the basis of practical answers; and how carefully the geologist has to guard against possible exceptions to his general rules. It will be unnecessary for my purpose to name or locate the property, or to deal in definite figures, and I shall describe only those features that bear upon the problem in hand.

The Problem

Intermittent work had opened a lead-silver vein along several hundred feet on both strike and dip. From these workings considerable rich ore had been gouged, while much low-grade material had been left. Poor management had lost the profit, and the property was put on the market. Prospective purchasers contracted for an examination by an experienced mining engineer, who, after careful sampling and exhaustive milling tests, concluded that if the rest of the vein along the strike and for a reasonable distance in depth were as good as that already opened up, the investment would be profitable, but that the ore in sight would not justify purchase unless there were a reasonable probability of the vein continuing to be valuable in parts yet unexplored. It was the old story of 'the mining chance,' but in this particular instance the investors wanted to know just how much of a chance there was. So the geologist was called in and directed to examine and report upon the possibilities of the vein along both strike and dip.

No question of this kind can be answered directly, for the occurrence and persistence of ore is dependent upon many factors. The vein must first be studied in respect to each of these, and the results then combined in the final answer.

General Statement

In this instance the question resolved itself into the following: 1. Is the formation in which the vein occurs favorable or unfavorable in the light of experience in a neighboring district? 2. Will the vein in depth pass into formations more or less favorable to good ore? 3. Is the fissure itself persistent or merely a small, localized fracture? 4. Granted that the fissure is persistent, did the primary mineralizing waters deposit in it in depth ore similar in kind and quantity to the primary ore in the present workings? 5. Is any of the ore in the present workings due to secondary enrichment? 6. What indications are there of troublesome faulting?

The vein occurs in the upper member of the same series of sediments that is found in a nearby district long famous for the persistence of its orebodies on both strike and dip. In this neighboring district, however, the production has all come from lower members of the series, and the upper member in which lies the vein discussed, has thus far shown little value. The prospective purchasers, therefore, feared they were dealing with a property in a 'barren formation.' Examination showed that this upper member is chemically and physically identical with the productive formations of the proved district, and could therefore be in itself an ore-bearer. That it is barren in the neighboring district is due not to the unfavorable nature of the formation itself, but to some extraneous geological condition. It was suggested that in the old district the solutions became chilled quickly enough to drop all of their metal content before reaching the upper members of the series, but that in the vicinity of the vein in question they had remained hot until they had risen higher in the series. In explanation of the different rates of cooling in the two localities it was pointed out that intrusive rocks are much more important in the vicinity of the new vein than in the old district. This last point of course reaches far into the realms of theory, but it shows how varying geological conditions may make a formation good in one district and bad in another, and drives home the fact that chemical and physical characters of a rock

mass are of more importance than its name or stratigraphic position.

Dip of the Vein

The vein, although lying almost parallel to the bedding planes, dips a bit more steeply, and therefore passes with depth into lower and lower beds of the formation, in which thin bedded shales predominate. The geologist feared at first that the vein, being so nearly parallel to the stratification, would upon passing into these shaly beds split up into numerous stringers, and the valuable parts become too widely spaced for profitable mining. But examination of the parts of the orebody exposed established the following facts: (1) the vein is not the result of filling a simple open fissure in massive beds, but is in large part the result of replacement working from a number of small parallel cracks; (2) the upper part of the formation, though in general more heavily bedded than the lower, contains some lenses of rock as shaly as any that the vein will meet in depth; (3) some of the best parts of the vein now exposed are the result of replacement of these shaly lenses. Recognition of this last fact required careful study of the details of vein structure, and its importance is obvious. Under the conditions obtaining in this locality, the shaly beds are evidently not unfavorable to the formation of good ore, and passage into thin bedded rocks in depth is not, therefore, an unfavorable indication.

The sediments of the district in question show many bedding plane seams or stringers of ore which are evidently not connected with any far reaching fissures, and which pinch out in all directions. One or two attempts to develop such seams have resulted disastrously. As the vein in question is similar to these seams in mineral content, and as it also is parallel to the strike of the bedding planes, and very nearly parallel to them in dip, the prospective purchaser feared that it would likewise prove only a seam and not a 'true fissure vein.'

A cover of soil prevented tracing the outcrop any great distance beyond the claim lines, and the requisite trenching has not been done. The deposit occurs in a definite bed of the sediments marked by a special color. It forms a distinct stratigraphic marker. In two other places, one a quarter of a mile, the other over half a mile away, openings have been made in the same distinctly colored bed on orebodies exactly like the one discussed, and parallel to the bedding planes in strike. There are, then, three veins, identical in character, 'lining up' with each other in strike. It might be rash to say that they are absolutely continuous, but it is safe to conclude that this particular colored stratum has been the locus of a well defined disturbance that has broken it along its strike for at least half a mile, and a disturbance of this extent is surely likely to affect the rocks to considerable depth. Moreover, the walls of the vein show slickensides and brecciation that are not found along the bedding plane seams that have proved unsatisfactory.

The conclusion, therefore, is that our vein lies along a line of extensive fissuring that is to be distinguished from the subordinate bedding plane slips in the vicinity, and that may with reason be expected to show the extent in depth that usually accompanies extensive fissuring. At the time of the examination no accurate locations or elevations were available, and the lining up of the widely separated veins was established largely upon stratigraphic grounds—another instance of the importance of general geology of the district.

Commercial considerations demand not only that the fissure persist in depth, but also that it carry ore; and in the case considered it was necessary that the fissure carry in depth ore of approximately the same grade as that exposed in the present workings.
